## Figures

Figure 2.1	Receipt of inheritances at each age, by cohort	19
Figure 2.2	Cumulative receipt of inheritances, by cohort	19
Figure 2.3	Distribution of total real value of inheritance(s) received	20
Figure 2.4	Inequality in the value of inheritance(s) received	21
Figure 2.5	Receipt of gifts at each age, by cohort	27
Figure 2.6	Cumulative receipt of gifts, by cohort	28
Figure 2.7	Distribution of total real value of gift(s) received	29
Figure 2.8	Inequality in the value of gift(s) received	29
Figure 2.9	Contribution of inheritances and gifts to wealth inequality	38
Figure 3.1	Prevalence of class membership in each domain, by sex, 2002–03 to 2012–13	
	a) Social and civic engagement	60
	b) Cultural engagement	60
	c) Consumption	60
	d) Health behaviours	61
Figure 3.2	Significant odds ratios of behaviour type, by age group	62
Figure 3.3	Significant odds ratios of behaviour type, by being female	63
Figure 3.4	Significant odds ratios of behaviour type, by marital status	63
Figure 3.5	Significant odds ratios of behaviour type, by wealth quintile	64
Figure 3.6	Significant odds ratios of behaviour type, by education	65
Figure 3.7	Significant odds ratios of behaviour type, by employment status	65
Figure 3.8	Significant odds ratios of behaviour type, by self-rated health	66
Figure 3.9	Significant odds ratios of behaviour type, by being frail	66
Figure 3.10	Significant odds ratios of behaviour type, by no car access	67
Figure 3.11	Significant odds ratios of behaviour type, by no access to public transport	67
Figure 3.12	Significant odds ratios of change in social and civic engagement, by education	71
Figure 3.13	Significant odds ratios of change in cultural engagement, by wealth quintile	72
Figure 3.14	Significant odds ratios of change in cultural engagement, by changes in frailty	75
Figure 4.1	Mean BMI at wave 2, by age group and sex	99
Figure 4.2	Change in mean BMI over eight years (2004–05 to 2012–13), by age group and sex	100
Figure 4.3	Mean waist circumference at wave 2, by age group and sex	101
Figure 4.4	Change in mean waist circumference over eight years (2004–05 to 2012–13), by age group and sex	101
Figure 4.5	Mean BMI at each wave, by retirement status and sex	103
Figure 4.6	Mean waist circumference at each wave, by retirement status and sex	103
Figure 4.7	Prevalence of obesity and central obesity, by wave and sex	107
Figure 4.8	Mean gait speed at each wave, by duration of obesity and sex	108
Figure 4.9	Mean gait speed at each wave, by duration of central obesity and sex	108
Figure 4.10	Mean hand grip strength at each wave, by duration of obesity and sex	109
Figure 4.11	Mean hand grip strength at each wave, by duration of central obesity and sex	109
Figure 4.12	Mean HbA1c at each wave, by duration of obesity and sex	110
Figure 4.13	Mean HbA1c at each wave, by duration of central obesity and sex	110
Figure 4.14	Mean minutes per hour of sedentary, light and moderate/vigorous physical activity during waking hours (7am–10pm) of weekdays	115
Figure 4.15	Mean duration of sedentary, light and moderate/vigorous activity per hour across all 24 hours of the day (averaged over weekdays): obese ELSA respondents	115
Figure 4.16	Mean duration of sedentary, light and moderate/vigorous activity per hour across all 24 hours of the day (averaged over weekdays): non-obese ELSA respondents	116

## Tables

Table 2.1	Receipt of inheritances, by cohort	16
Table 2.2	Expectations of receiving an inheritance in future	17
Table 2.3	Value of inheritance(s) received, by donor	21
Table 2.4	Individual characteristics associated with the probability of having received an inheritance, and the total value of inheritances received	23
Table 2.5	Receipt of substantial gifts, by cohort	26
Table 2.6	Individual characteristics associated with the probability of having received a gift, and the total value of gifts received	30
Table 2.7	Composition of current net wealth	33
Table 2.8	Contribution of inheritance(s) to current net wealth	35
Table 2.9	Contribution of gift(s) to current net wealth	36
Table 2.10	Contribution of total transfers to current net wealth	37
Table 2.11	Shares of wealth held by parts of the current net wealth distribution	39
Table 2.12	Inequality in net wealth including and excluding transfers	39
Table 2.13	Sensitivity of main results to interest rate assumption	40
Table 2.14	Sensitivity of main results to assumption on proportion saved	42
<i>Appendix 2A</i>		<i>46</i>
Table 2A.1	Percentage of individuals with different characteristics who received an inheritance, and the average value received	
Table 2A.2	Individual characteristics associated with probability of having received a parental inheritance, and total value of parental inheritances received	
Table 2A.3	Individual characteristics associated with probability of having received a non-parental inheritance, and total value of non-parental inheritances	
Table 2A.4	Percentage of individuals with different characteristics who received a substantial gift, and the average value received	
Table 2A.5	Impact of alternative interest rate assumptions on estimated contribution of transfers to current net wealth	
Table 2A.6	Impact of alternative savings rate assumptions on estimated contribution of transfers to current net wealth	
Table 3.1	Lifestyle behaviour changes across transition points, by dimension, 2002–03 to 2012–13	68
Table 3.2	Change in employment status, marital status, frailty and access to transport across transition points, 2002–03 to 2012–13	70
<i>Appendix 3A</i>		<i>80</i>
Table 3A.1	Proportions of respondents for each item used to construct the latent classes of social and civic engagement, by wave, 2002–03 to 2012–13	
Table 3A.2	Proportions of respondents for each item used to construct the latent classes of cultural engagement, by wave, 2002–03 to 2012–13	
Table 3A.3	Mean spending (durables, food and clothes) and proportions of respondents for holiday items used to construct the latent classes of consumption behaviour, by wave, 2004–05 to 2012–13	
Table 3A.4	Likelihood of class membership, by socio-demographic, socio-economic and health factors and access to transport	
Table 3A.5	Change in social and civic engagement, by baseline characteristics	
Table 3A.6	Change in cultural engagement, by baseline characteristics	
Table 3A.7	Change in consumption, by baseline characteristics	
Table 3A.8	Change in smoking and drinking behaviour, by baseline characteristics	
Table 3A.9	Change in physical activity, by baseline characteristics	
Table 3A.10	Change in social and civic engagement, by change in life circumstances across transition points	
Table 3A.11	Change in cultural engagement, by change in life circumstances across transition points	
Table 3A.12	Change in consumption, by change in life circumstances across transition points	

Table 3A.13	Change in smoking and drinking behaviour, by change in life circumstances across transition points	
Table 3A.14	Change in physical activity, by change in life circumstances across transition points	
<i>Appendix 4A</i>		122
Table 4A.1	Means of and changes in BMI, by wealth and sex	
Table 4A.2	Means of and changes in waist circumference, by wealth and sex	
Table 4A.3	Mean $\pm$ SD change in BMI and waist circumference between wave 2 and wave 6, by retirement status	
Table 4A.4	Linear regression coefficients for the association between retirement and change in BMI and waist circumference between wave 2 and wave 6	
Table 4A.5	Mean $\pm$ SD change in BMI and waist circumference between wave 2 and wave 6, by retirement status and wealth	
Table 4A.6	Linear regression coefficients for the interaction between retirement and wealth on change in BMI and waist circumference between wave 2 and wave 6	
Table 4A.7	Mean $\pm$ SD change in BMI and waist circumference between wave 2 and wave 6, by retirement status and level of physical activity in the workplace	
Table 4A.8	Linear regression coefficients for the interaction between retirement and level of physical activity in the workplace on change in BMI and waist circumference between wave 2 and wave 6	
Table 4A.9	Duration of obesity, by age and sex	
Table 4A.10	Duration of central obesity, by age and sex	
Table 4A.11	Duration of obesity, by wealth and sex	
Table 4A.12	Duration of central obesity, by wealth and sex	
Table 4A.13	Logistic regression for the relationship between duration of obesity and gait speed: people aged 60 and over at wave 2	
Table 4A.14	Logistic regression for the relationship between duration of central obesity and gait speed: people aged 60 and over at wave 2	
Table 4A.15	Logistic regression for the relationship between duration of obesity and hand grip strength	
Table 4A.16	Logistic regression for the relationship between duration of central obesity and hand grip strength	
Table 4A.17	Logistic regression for the relationship between duration of obesity and glycated haemoglobin (HbA1c)	
Table 4A.18	Logistic regression for the relationship between duration of central obesity and glycated haemoglobin (HbA1c)	
Table 4A.19	Mean $\pm$ SD BMI and waist circumference at wave 6, by sex	
Table 4A.20	Prevalence of obesity at wave 6, by wealth	
Table 4A.21	Prevalence of obesity according to self-reported and objective physical activity at wave 6	
Table 4A.22	Logistic regression for the relationship between self-reported and objective physical activity and obesity, wave 6	
Table 4A.23	Logistic regression for the relationship between self-reported and objective physical activity and central obesity, wave 6	
Table 5.1	Respondents, by sample type: Cohort 1	141
Table 5.2	Core member respondents, by situation in wave 6 (2012–13): Cohort 1	141
Table 5.3	Respondents, by sample type: Cohort 3	141
Table 5.4	Core member respondents, by situation in wave 6 (2012–13): Cohort 3	142
Table 5.5	Respondents, by sample type: Cohort 4	142
Table 5.6	Core member respondents, by situation in wave 6 (2012–13): Cohort 4	143
Table 5.7	Respondents, by sample type: Cohort 6	143
Table 5.8	Core member respondents, by situation in wave 6 (2012–13): Cohort 6	143
Table 5.9	Reasons for non-response: core members in Cohort 1	145
Table 5.10	Reasons for non-response: core members in Cohort 3	145
Table 5.11	Reasons for non-response: core members in Cohort 4	145
Table 5.12	Reasons for non-response: core members in Cohort 6	145

Table 5.13	Status of original Cohort 1 core members at wave 6	146
Table 5.14	Status of original Cohort 3 core members at wave 6	147
Table 5.15	Status of original Cohort 4 core members at wave 6	147
Table 5.16	Achieved sample of Cohort 1 core members, by age in 2012–13 and sex	148
Table 5.17	Wave 6 (2012–13) main interview response for Cohort 1 core members who took part in waves 1–5, by age in 2002–03 and sex	148
Table 5.18	Achieved sample of Cohort 3 core members, by age in 2012–13 and sex	149
Table 5.19	Achieved sample of Cohort 4 core members, by age in 2012–13 and sex	149
Table 5.20	Achieved sample of Cohort 6 core members, by age in 2012–13 and sex	150
Table 5.21	Proxy interview sample (Cohort 1), by age in 2012–13 and sex	150
Table 5.22	Achieved nurse visits with core members from all cohorts, in 2012–13, by age and sex	151
Table 5.23	Achieved nurse visits with core members from all cohorts as a percentage of wave 6 interviews (2012–13), by age	151
Table 5.24	Reasons for non-response to nurse visit for core members from all cohorts	152
Table 5.25	Household population estimates	156
Table 5.26	Achieved (combined) sample of core members, by age in 2012–13 and sex	157

## Reference tables

<i>Economics domain tables</i>		174
Table E1a	Mean unequivalised net weekly family income, by age and family type: wave 6	
Table E1b	Mean equivalised net weekly family income, by age and sex: wave 6	
Table E2a	Distribution of total net weekly unequivalised family income, by age and family type: wave 6	
Table E2b	Distribution of total net weekly equivalised family income, by age and sex: wave 6	
Table E3	Mean and median wealth, by age and family type: wave 6	
Table E4	Distribution of total net non-pension wealth, by age and family type: wave 6	
Table E5a	Private pension membership, by age and sex (workers and non-workers under state pension age): wave 6	
Table E5b	Private pension membership, by age and sex (workers under state pension age): wave 6	
Table E6	Mean equivalised weekly household spending, by age and family type: wave 6	
Table E7	Mean self-reported chances of having insufficient resources to meet needs at some point in the future, by age, sex and income group: wave 6	
Table E8	Labour market participation, by age, sex and wealth group (individuals aged under 75 only): wave 6	
Table E8N	Sample sizes for Table E8	
Table E9	Mean self-reported chances of working at future target ages, by age, sex and wealth: wave 6	
Table E9N	Sample sizes for Table E9	
Table E10	Whether health limits kind or amount of work, by age, sex and wealth: wave 6	
Table E11	Mean self-reported chances of health limiting ability to work at age 65 (workers aged under 65 only), by age, sex and wealth group: wave 6	
Table E11N	Sample sizes for Table E11	
Table EL1a	Mean equivalised weekly family TOTAL income, by baseline (wave 1) age and family type	
Table EL1b	Mean equivalised weekly family EARNINGS, by baseline (wave 1) age and family type	
Table EL1c	Mean equivalised weekly family PRIVATE PENSION income, by baseline (wave 1) age and family type	
Table EL1d	Mean equivalised weekly family STATE PENSION AND BENEFIT income, by baseline (wave 1) age and family type	
Table EL1e	Mean equivalised weekly family ASSET AND OTHER income, by baseline (wave 1) age and family type	
Table EL2a	Mean equivalised weekly family TOTAL income, by baseline (wave 1) age and education	

Table EL2b	Mean equivalised weekly family EARNINGS, by baseline (wave 1) age and education
Table EL2c	Mean equivalised weekly family PRIVATE PENSION income, by baseline (wave 1) age and education
Table EL2d	Mean equivalised weekly family STATE PENSION AND BENEFIT income, by baseline (wave 1) age and education
Table EL2e	Mean equivalised weekly family ASSET AND OTHER income, by baseline (wave 1) age and education
Table EL3	Interquartile ratio (p75/p25) of total equivalised net family income, by baseline (wave 1) age and family type
Table EL4a	Persistency of making pension contributions in waves when observed under SPA, by age, sex and wealth group: aged under SPA and employed or self-employed at baseline only
Table EL4b	Persistency of making pension contributions in waves when observed under SPA, by age, sex and wealth group: employed or self-employed in all waves observed below state pension age
Table EL5	Persistence of self-reported financial difficulties and persistence of managing very well financially, by age and family type
Table EL6a	Persistence of having too little money to do three or more items of the material deprivation index (waves 2–6), by education and family type: aged 50–SPA
Table EL6b	Persistence of having too little money to do three or more items of the material deprivation index (waves 2–6), by education and family type: aged SPA–74
Table EL6c	Persistence of having too little money to do three or more items of the material deprivation index (waves 2–6), by education and family type: aged 75+
Table EL7a	Percentage of men employed or self-employed at baseline (wave 1) and, of those, percentage still in employment or self-employment at waves 2–6, by wealth group and age
Table EL7b	Percentage of women employed or self-employed at baseline (wave 1) and, of those, percentage still in employment or self-employment at waves 2–6, by wealth group and age
Table EL8	Percentage not employed or self-employed at baseline (wave 1) and, of those, percentage in employment or self-employment at waves 2–6, by age and sex
Table EL9a	Persistency of health problem limiting ability to work in waves 1–6, by wealth group and age: men aged under 75 at baseline only
Table EL9b	Persistency of health problem limiting ability to work in Waves 1–6, by wealth group and age: women aged under 75 at baseline only

Table S1a	Marital status, by age and sex: wave 6
Table S1b	Marital status, by wealth group and sex: wave 6
Table S2a	Ethnicity, by age and sex: wave 6
Table S2b	Ethnicity, by wealth group and sex: wave 6
Table S3a	Use internet and/or email, by age and sex: wave 6
Table S3b	Use internet and/or email, by wealth group and sex: wave 6
Table S4a	Mean total hours of TV watched per week, by age and sex: wave 6
Table S4b	Mean total hours of TV watched per week, by wealth group and sex: wave 6
Table S5a	Taken holiday (in UK or abroad) in the last 12 months, by age and sex: wave 6
Table S5b	Taken holiday (in UK or abroad) in the last 12 months, by wealth group and sex: wave 6
Table S6a	Use of public transport, by age and sex: wave 6
Table S6b	Use of public transport, by wealth group and sex: wave 6
Table S7a	Use of private transport, by age and sex: wave 6
Table S7b	Use of private transport, by wealth group and sex: wave 6
Table S8a	Finds it difficult to get to services, by age and sex: wave 6
Table S8b	Finds it difficult to get to services, by wealth group and sex: wave 6
Table S9a	Voluntary work frequency, by age and sex: wave 6
Table S9b	Voluntary work frequency, by wealth group and sex: wave 6
Table S10a	Cared for someone in the last month, by age and sex: wave 6

Table S10b	Cared for someone in the last month, by wealth group and sex: wave 6
Table S11a	Receives help with mobility, by age and sex: wave 6
Table S11b	Receives help with mobility, by wealth group and sex: wave 6
Table S12a	Mean number of close relationships with children, family and friends, by age and sex: wave 6
Table S12b	Mean number of close relationships with children, family and friends, by wealth group and sex: wave 6
Table S13a	Self-perceived social standing in society, by age and sex: wave 6
Table S13b	Self-perceived social standing in society, by wealth group and sex: wave 6
Table S14a	Mean self-perceived chance of living to 85, by age and sex: wave 6
Table S14b	Mean self-perceived chance of living to 85, by wealth group and sex: wave 6
Table SL1a	Percentage married or remarried at baseline (wave 1) and, of those, percentage still married at waves 2–6, by age and sex
Table SL1b	Percentage married or remarried at baseline (wave 1) and, of those, percentage still married at waves 2–6, by wealth group and sex
Table SL2a	Percentage using internet and/or email at baseline (wave 1) and, of those, percentage still using internet and/or email at waves 2–6, by age and sex
Table SL2b	Percentage using internet and/or email at baseline (wave 1) and, of those, percentage still using internet and/or email at waves 2–6, by wealth group and sex
Table SL2c	Percentage not using internet and/or email at baseline (wave 1) and, of those, percentage using internet and/or email at waves 2–6, by age and sex
Table SL2d	Percentage not using internet and/or email at baseline (wave 1) and, of those, percentage using internet and/or email at waves 2–6, by wealth group and sex
Table SL3a	Percentage been on holiday in the last year at baseline (wave 1) and, of those, percentage still been on holiday in the last year at waves 2–6, by age and sex
Table SL3b	Percentage been on holiday in the last year at baseline (wave 1) and, of those, percentage still been on holiday in the last year at waves 2–6, by wealth group and sex
Table SL4a	Percentage using public transport at baseline (wave 1) and, of those, percentage still using public transport at waves 2–6, by age and sex
Table SL4b	Percentage using public transport at baseline (wave 1) and, of those, percentage still using public transport at waves 2–6, by wealth group and sex
Table SL4c	Percentage not using public transport at baseline (wave 1) and, of those, percentage using public transport at waves 2–6, by age and sex
Table SL4d	Percentage not using public transport at baseline (wave 1) and, of those, percentage using public transport at waves 2–6, by wealth group and sex
Table SL5a	Percentage with access to a car or van at baseline (wave 1) and, of those, percentage still with access to a car or van at waves 2–6, by age and sex
Table SL5b	Percentage with access to a car or van at baseline (wave 1) and, of those, percentage still with access to a car or van at waves 2–6, by wealth group and sex
Table SL6a	Percentage volunteering at baseline (wave 1) and, of those, percentage still volunteering at waves 2–6, by age and sex
Table SL6b	Percentage volunteering at baseline (wave 1) and, of those, percentage still volunteering at waves 2–6, by wealth group and sex
Table SL6c	Percentage not volunteering at baseline (wave 1) and, of those, percentage volunteering at waves 2–6, by age and sex
Table SL6d	Percentage not volunteering at baseline (wave 1) and, of those, percentage volunteering at waves 2–6, by wealth group and sex
Table SL7a	Percentage not caring for someone at baseline (wave 1) and, of those, percentage caring for someone at waves 2–6, by age and sex
Table SL7b	Percentage not caring for someone at baseline (wave 1) and, of those, percentage caring for someone at waves 2–6, by wealth group and sex

# 1. Introduction

**Andrew Steptoe** *University College London*

**Michael Marmot** *University College London*

**David Batty** *University College London*

The remarkable demographic shifts towards an older population have continued to evolve since the English Longitudinal Study of Ageing (ELSA) began in 2002. The number of people aged 50 and over living in England has increased from 16.56 million in 2002 to 18.65 million in 2012, with the proportion of individuals aged 80 and older rising from 4.3% to 4.7%. Across the world, the number of people aged 65 and over increased by 25% between 2000 and 2010, and it is expected to double again by around 2030. These trends are a cause for celebration and are a testament to continuing improvements in public health, nutrition, education, health and social care. Older people make a major contribution to our society that is poorly recognised, in supporting younger generations financially, practically and in the transmission of wisdom, in volunteering, and in active engagement with local and national political issues. Nevertheless, the ageing of the population brings with it a series of major social and policy issues such as income security for older people, social protection, the prevention of impoverishment and social isolation in old age, access to quality health care, effective and affordable social care, the promotion of age-friendly environments that allow independent living, the prevention of discrimination against older people, and securing the human rights of the ageing population. Additionally, the burden of disease and disability increases with age, since most of the chronic diseases of public health importance are more common among the elderly. Understanding these processes is a key challenge that requires a robust and reliable evidence base detailing the experience of people as they age.

ELSA was designed to fulfil this need for high-quality data that integrate information about the economic, social, psychological, community and health experience of older people in England. We recruited a representative sample of men and women aged 50 and older, and have reassessed the sample every two years since then. This report describes findings from the latest wave of data collection, conducted in 2012–13. From the beginning, ELSA has been a multidisciplinary study with input from epidemiology, economics, demography, psychology, sociology and clinical medicine, tracking people as they prepare for and move into retirement and older age. The study is structured to inform policy as well as collect data that can be used by academic researchers. Thus the information in ELSA is relevant to pension policies and the changes in state pension age (SPA), the funding of social care, labour market participation, consequences of the restructuring of the National Health Service, policies designed to reduce social isolation and discrimination, public transport access, and many other issues. Researchers both in the UK and across the world are increasingly turning to ELSA to address topics such as social inequalities in health, subjective well-being, cognitive decline, digital

inclusion, cross-national differences in health, the impact of the financial crisis on wealth and well-being, sleep, the health consequences of sedentary behaviour, and genetic factors in disease risk.

In wave 6, information was collected from 10,601 participants in ELSA, including 9,169 ‘core’ participants (age-eligible sample members who participated the first time they were approached to join the study). The sample included 5,659 individuals who have remained in the study from the start, plus refreshment cohorts first interviewed in wave 3 (2006–07), wave 4 (2008–09) and wave 6 (2012–13). The main reason for the refreshment cohorts is to ensure representation of people in their 50s, since the youngest participants from wave 1 are now over 60 years old. Data were collected using a computer-aided personal interview (CAPI) in the participants’ homes, supplemented by a self-completion questionnaire. In addition, a nurse visit was conducted for the assessment of physical functional status and biomarkers. This is the third round of biomarker collection (previous assessments took place in 2004–05 and 2008–09), and ELSA is currently the only large-scale multidisciplinary population study of older people in the world to contain such data.

As in previous waves, the ELSA team have tried to balance four issues in data collection. These are: the need for repeat measures of the same variables over waves, in order to build up the time series; the need to move ever closer to harmonisation of measures with other studies internationally, notably the Health and Retirement Study (HRS); the time constraints in data collection, and the importance of ensuring that the protocol is not so extensive as to be prohibitively costly and to overtax our older participants; and the drive to assess new issues and concepts that are relevant to population ageing against innovations and new variables that have not previously been included. In wave 6, we were successful in introducing a number of innovative measures that have broadened the scope of the study, including:

- a new module on social care, including information on the type of care and its funding;
- new measures of intergenerational transfers;
- a comprehensive set of measures about sexual attitudes and behaviour;
- new measures of fluid intelligence, based on methods developed in the HRS;
- more detailed questions about internet use and digital literacy;
- new measures of subjective well-being, blending the approach used by the Office for National Statistics (ONS) in its ‘Measuring National Well-Being’ programme with affect and time use methods developed in collaboration with colleagues in HRS;
- assessment of polypharmacy;
- additional biomarkers, and assessment of objective physical activity with accelerometers in a subsample.

It is not possible within a single report to cover all the topics and variables assessed in wave 6. We have therefore structured the report around three substantive chapters that address important issues in the economic, social and

health domains (Chapters 2 to 4). These are coupled with a detailed set of tables (Chapters E, S and H) that summarise data collected in these domains, including cross-sectional analyses of wave 6 and longitudinal analyses of the study members who completed all six waves of assessment. This is a convenient way of presenting more results than is possible within separate chapters, though there are still important topics that we have not been able to include.

The topics of the three thematic chapters were selected during discussion with the representatives of the government departments that contribute to the funding of ELSA. They were chosen because of their importance to both policy and scientific research.

## **Intergenerational financial transfers**

Understanding how intergenerational monetary and financial transfers are distributed and what impact they have on wealth is an important policy issue. Transfers between parents, children and grandchildren have a major impact on wealth and standard of living during retirement. With increasing life expectancy, pensions and other savings have to last longer, and older people may be more reliant on inheritances and gifts than their predecessors. There is intense public interest in the social distribution of economic resources, and Thomas Piketty's book *Capital in the Twenty-First Century* has stimulated vigorous debate around the argument that there are widening differences in income and wealth across society. Good evidence on this topic from the UK has been limited, with reliance on estate and inheritance data following death. But people not only receive inheritances but may also be given substantial gifts by donors when they are still alive. Wave 6 of ELSA included questions on the lifetime receipt of inheritances and substantial gifts, permitting a fuller account of intergenerational transfers and their impact on wealth. The results in Chapter 2 address a number of issues with greater precision than has been possible before.

### **How common are inheritances and gifts?**

The analyses in Chapter 2 indicate that just over a quarter of ELSA participants had received an inheritance in their lifetime, and 7% had received a gift worth £1,000 or more in today's money. Some of the inheritances were very large, with one-in-ten of those who had an inheritance receiving more than £200,000, while 15% inherited less than £5,000. The value of gifts varied even more widely, with around a quarter of recipients receiving less than £2,000, while one-in-twenty received more than £100,000. Most of these inheritances and gifts were from parents, with a smaller proportion from grandparents or uncles and aunts.

An interesting issue is whether the inheritances and gifts are more common in cohorts born later within ELSA. We find good evidence that the participants in their 50s and 60s are more likely to have received inheritances and substantial gifts than those in their 70s and older, and that their expectations of future inheritances are also greater. This is probably due to the increase in homeownership and greater wealth among the parents of the younger ELSA participants compared with earlier generations.

## **Inequalities in intergenerational transfers**

The results of these new analyses clearly document large inequalities in both the receipt and value of inheritances and gifts. Respondents with higher education and greater income were more likely to have received inheritances and gifts, and the value of these transfers was greater. These findings indicate that intergenerational transfers would reinforce, and potentially widen, economic and social inequalities. However, the situation is not so simple. Although the absolute distribution of the worth of inheritances and gifts is greater in more affluent sectors of the population, the relative contribution of these transfers to wealth is greater for those at the bottom of the wealth distribution.

Analyses of this sort raise many additional questions. The data in ELSA concern inheritances and gifts received by participants in the study, and we would dearly like to know about gifts from ELSA participants to their children, grandchildren and others. This notwithstanding, the results presented in Chapter 2 are an important first step towards a better understanding of relationships between generations.

## **The evolution of lifestyles**

### **Repositioning lifestyle in older people**

Several decades of population-based studies have established that health behaviours, most notably smoking, alcohol intake, physical inactivity and poor diet – both individually and collectively – are related to reduced life expectancy and an increased risk of psychological and physical illness. More recently, research has shown that lifestyle in its broadest sense, comprising not only these behaviours but also civic and cultural participation, may also influence health and longevity. As a result, several campaign groups and government initiatives aim to have lower levels of social engagement, particularly loneliness, recognised as a major public health issue. For example, the UK government launched a programme in 2010 aimed at supporting people aged 60 and older who are at risk of loneliness and social isolation, funding more than 450 local initiatives across the country. Chapter 3 of this report uses a combination of health behaviours, consumption and civic, social and cultural engagement (activities such as going to cinemas, museums or theatres) to define lifestyles at older ages. It describes these areas in more detail and shows both the size of the problem – that is, the prevalence of unfavourable levels of these characteristics – and the determinants of the lifestyle behaviours.

### **Lifestyle and how we age**

While up to 40% of study members had very little physical activity at wave 6, levels of smoking and daily drinking were actually very low, a not altogether uncommon result in older people. Taking the various waves of data collection together allowed us to explore trajectories, with the finding that these health behaviours were exceptionally stable over the older-age life course such that the majority of study members did not change their health-related habits. The high levels of sedentary behaviour pre-echo the findings in Chapter 4, and the

lack of change in physical activity levels over time may partially explain the stability of weight in cohort members as they age. Illness and frailty emerged as important determinants of lifestyle. Both are age-dependent, occurring more frequently at the higher end of the age spectrum. These health states in the ELSA members partly explained our finding that, relative to the younger people in ELSA, older people tended to report lower levels of civic and cultural engagement, an effect that was particularly pronounced from 70 years of age onwards. On a more positive note, it was also the case that, contrary to our hypotheses, retirement was associated with *increased* social and civic engagement. Being widowed also had surprising effects; although some people showed reductions in social and civic activity, we found evidence that cultural activity increased as well. The explanation for this is unclear; however, it seems plausible that study participants might have been constrained by their partner's preferences while being married, or perhaps their cultural activity had been limited by caring responsibilities that diminished after their partner had died.

Perhaps not surprisingly, access to transport has a significant influence on social, civic and cultural activity, with both car ownership and public transport use being important. As people grow older and stop having access to a car, their cultural activity diminishes greatly. The findings highlight the importance of older people's bus passes in encouraging sustained cultural engagement as part of a healthy and active lifestyle.

### **Socio-economic factors and lifestyle at older ages**

The analyses in Chapter 3 provided further evidence of the crucial role of socio-economic factors in the lives of older people. Focusing on our measure of wealth, which was designed to capture multiple financial domains that are particularly relevant to older people (savings, investments, property value, business assets and so on), there were clear gradients in social, civic and cultural engagement, consumption and health behaviours: better-off respondents are more socially and culturally active, buy more goods and travel more, are more physically active and smoke less. The only facet of lifestyle in which richer participants appear to be disadvantaged is an increased likelihood of drinking daily. Education level, another indicator of socio-economic position, is also linked with social, civic and cultural engagement, but relationships with health behaviour are weaker than for wealth. Richer participants also remain more persistently engaged in cultural activity over time, and, in analyses of people who smoked, were more likely than other groups to quit the habit.

## **Trends in obesity**

The considerable social, economic and health burden of obesity has been well documented, leading to calls for urgent preventative action from health insurers, businesses, governments and other stakeholders. Importantly, the unfavourable consequences of higher weight do not seem to be confined to people who are obese: an elevated risk of a range of negative health and social outcomes is also apparent in overweight people. Abdominal or central obesity, indexed in ELSA by waist circumferences, confers additional risk for

cardiovascular disease and diabetes over and above general obesity. The Department of Health policy outlined in *Healthy Lives, Healthy People: A Call to Action on Obesity in England* (2011) highlighted the ambition to stimulate a downward trend in adult weight by 2020. Obesity and its prevention and control is a major priority for Public Health England.

### **How can ELSA advance understanding in obesity research?**

Crucial to the planning of future health and social care provision in the UK is the contemporary quantification of obesity (and overweight) prevalence in a representative sample of the general population. While this is possible in several UK-based cross-sectional studies, a particular advantage offered by ELSA is that we can also understand trajectories in obesity, due to the very unusual repeat measurement of weight over eight years. While cross-sectional data provide ‘snapshot’ information at a single point in time, longitudinal studies that follow a group of individuals across the life course tell us about the natural history of a set of characteristics, including adiposity. ELSA is perhaps unique in this regard. A further advantage of the multidisciplinary nature of ELSA is that we have an array of social, psychological and physical data on participants which allow us to understand the determinants of obesity and whether these differ across certain groups (for example, the socially disadvantaged or those with chronic illness). In the continued absence of effective pharmacological treatment, primary prevention of obesity – the identification of causes – is crucial if successful policy interventions are to be implemented.

### **Prevalence, trajectories and determinants of obesity**

Adiposity was ascertained in ELSA using body mass index (a standard measure of weight which takes into account height) and waist circumference. It is of great concern that, at wave 2 (2004–05), around three-quarters of men and women in ELSA could be classified as either overweight or obese and, in waves 4 (2008–09) and 6 (2012–13), the prevalence has increased marginally for both markers of adiposity utilised in this study. We therefore find no evidence in this large sample of older men and women of any reductions in the prevalence of obesity over this eight-year period; indeed, in most age categories, obesity and waist circumference have increased.

The analyses in Chapter 4 show clear associations between obesity, functional capacity and markers of health risk. Sustained obesity over the eight-year study period was – perhaps not surprisingly – associated with increases in glycated haemoglobin (a risk marker for diabetes). However, we also found that persistently obese study members experienced faster declines in key indicators of healthy ageing. Thus, people who were persistently obese showed more rapid loss of walking speed (an important measure of functional capacity) and grip strength (an indicator of muscle strength). This indicates that, as well as being important health issues in their own right, obesity and central adiposity have implications for broader health and functional outcomes at advanced ages. These analyses illustrate the benefits of continuing to measure adiposity trends in ELSA over the forthcoming years.

A novel feature in wave 6 of ELSA was to include objective measures of physical activity in a subgroup of ELSA participants. With physical activity

being a multidimensional behaviour, standard self-report may provide inaccurate data, particularly among older people, whose physical exertion tends to be of low intensity (for example, walking), occurring as part of everyday life rather than in easily recalled episodes of exercise. Until recently, accelerometry technologies have not enabled us objectively to measure physical activity and sedentary behaviours (including sleep) in sufficiently high numbers at realistic cost for meaningful analyses. The accelerometers provided useful data that complemented our self-report measures. It was particularly striking how many hours per day were spent in sedentary activities, which involve very little energy expenditure. The objective measures of activity showed closer associations with obesity than did self-report measures, which perhaps confirms the advantages of this technology.

Physical exercise habits often change with the occurrence of major life events such as retirement, and this may have implications for weight trajectories. The impact of retirement on health and social factors is particularly germane to pension policy and central government initiatives to extend working lives led by the Department for Work and Pensions. While retirement did not appear in these analyses to be related to weight gain across the complete ELSA sample, greater increases in body mass index and waist circumference were evident in those retirees who were less wealthy.

Clearly there is much useful work to be done in the context of obesity research using the ELSA resource. The focus of future work is unlikely to lie in further clarifying the health consequences of obesity and weight gain – already a well-researched area. Rather, priority might lie in the links with physical and cognitive function trajectories, social connections, pre-adult environment (including adversity), and major life events such as retirement, widowhood and the onset of chronic disease.

## **Methodology**

The fieldwork, sample design, response rates, content of the ELSA interviews and weighting strategies used in wave 6 are described in Chapter 5. A brief summary of the design is given here. The original ELSA sample was drawn from households that had responded to the Health Survey for England (HSE) in the years 1998, 1999 and 2001. Individuals were eligible if they were born before 1 March 1952 and were, at the time of the ELSA 2002–03 interview, still living in a private residential address in England. In addition, we interviewed partners under the age of 50 years, and new partners who had moved into the household since HSE. The participants who were recruited for the first wave of ELSA or have since become partners of such people are known as Cohort 1.

Wave 2 of ELSA took place in 2004–05, and the core members and their partners were eligible for interview provided they had not refused any further contact after the first interview. In the third wave, our aim was to supplement the original cohort with people born between 1 March 1952 and 1 March 1956 so that the ELSA sample would again cover ages 50 and over. The new recruits were sourced from the 2001–04 HSE years. Wave 4 took place in 2008–09 and the original cohort was supplemented with a refreshment sample

of HSE respondents born between 1 March 1933 and 28 February 1958, taken from HSE 2006. The fieldwork for wave 5 was carried out in 2010–11.

Data collection on wave 6 was carried out in 2012–13. In addition to the cohorts included in previous waves, we added a refreshment sample of individuals born between 1 March 1956 and 28 February 1962. They had previously participated in the HSE in 2009, 2010 or 2011. Again, both core members and their partners were interviewed, but the analyses in this report are largely based on data provided by the core members only.

We carried out a face-to-face interview and a self-completion assessment in all waves. In waves 2 and 4, and again in the most recent wave (6), we also conducted a nurse visit.

The broad topics that have been covered in every wave include household composition, employment and pension details, housing, income and wealth, self-reported doctor-diagnosed diseases and symptoms, tests of cognitive performance and of gait speed, health behaviours, social contacts and selected activities, and a measure of quality of life. As noted on page 2, new material was added in wave 6 related to a number of issues.

Academic researchers, policy analysts and others interested in ageing research who are registered with the Economic and Social Data Service Archive can access the ELSA data sets, via the download service or via the online Nesstar software tool.

- ELSA data sets: [www.esds.ac.uk/findingData/elsaTitles.asp](http://www.esds.ac.uk/findingData/elsaTitles.asp)
- ESDS Nesstar Catalogue: [nesstar.esds.ac.uk/webview/index.jsp](http://nesstar.esds.ac.uk/webview/index.jsp)

## Reporting conventions

The analyses in this report mostly use information from the core members of ELSA. The remaining data come from interviews with the partners of core members. Proxy interviews have been excluded, mainly because a much-reduced set of information is available for these people.

The cross-sectional analyses in reference tables E, S and H have been weighted for non-response, so that estimates should reflect the situation among people aged 50 and over in England. The longitudinal analysis tables use longitudinal weights, as described in Chapter 5.

Statistics in cells with between 30 and 49 observations are indicated by the use of square brackets. Statistics that would be based on fewer than 30 observations are omitted from the tables; the number eligible is given but a dash is placed in the cell where the statistic would otherwise be placed.

## Future opportunities using ELSA

The fieldwork for wave 7 of ELSA began in May 2014. The study is at the leading edge in both survey methodology and content, with new forms of data collection and new topics being introduced as the study progresses. The value of ELSA to research and policy increases as the longitudinal aspect is extended. Ultimately, however, the value of the study depends on its use by

research and policy analysts, and their exploration of ELSA's rich multidisciplinary data set. For a list of publications and reports and other documentation concerning ELSA, please go to our website: <http://www.elsa-project.ac.uk/>.

## **Acknowledgements**

ELSA is a highly multidisciplinary study that would not have been achievable without the efforts of a large number of people. The study is led by a small committee chaired by Professor Andrew Steptoe and made up of Professor James Banks, Dr David Batty, Dr Margaret Blake, Professor Sir Richard Blundell, Professor Sir Michael Marmot, Professor James Nazroo and Zoë Oldfield, and Dr Nina Rogers manages the study. The past input from Sam Clemens and Andrew Phelps to this committee is gratefully acknowledged.

We recognise and greatly appreciate the support we have received from a number of different sources. We are most indebted to those people who have given up their time and welcomed interviewers and nurses into their homes on so many occasions. We hope that our participants will in future years continue to commit to ELSA, helping us to understand further the dynamics in health, wealth and lifestyle of the ageing population. Another vital ingredient to the success of the study is the commitment of the more than 300 dedicated interviewers and nurses involved in collecting the data.

ELSA is coordinated by four main institutions: University College London (UCL), the Institute for Fiscal Studies (IFS), the University of Manchester and NatCen Social Research. There is also close collaboration with Dr Nicholas Steel from the University of East Anglia. The study involves a great many individuals in each of these institutions, some of whom have contributed to authorship of the chapters and reference tables in this report.

We would like to express our gratitude to Sheema Ahmed, for her careful administrative work on the study. With regard to this report, particular thanks are due to Judith Payne for her fastidious copy-editing of the final manuscript and to Emma Hyman, Benita Rajania and Stephanie Seavers for their continued guidance of the report during the different stages of publication.

The ELSA research team has been guided by two separate groups. First is a group of leading national and international consultants who have provided specialist advice. We are very grateful to this group, which includes Lisa Berkman (Harvard), Axel Börsch-Supan (Munich Center for the Economics of Aging), Nicholas Christakis (Yale), Hideki Hashimoto (University of Tokyo), Michael Hurd (RAND), Arie Kapteyn (University of Southern California), Hal Kendig (University of Sydney), David Laibson (Harvard), Kenneth Langa (University of Michigan), Johan Mackenbach (Erasmus University Rotterdam), John McArdle (University of Southern California), David Melzer (Peninsula College of Medicine and Dentistry), Marcus Richards (UCL), Kenneth Rockwood (Dalhousie University), Paul Shekelle (RAND), Johannes Siegrist (University of Dusseldorf), James Smith (University of Southern California), Robert Wallace (University of Iowa), David Weir (University of Michigan) and Robert Willis (University of Michigan). Second is the advisory group to the study, which is chaired by Baroness Sally Greengross. Members

## *Introduction*

over this period have included Michael Bury, Richard Disney, Emily Grundy, Ruth Hancock, Sarah Harper, Tom Kirkwood, Carol Propper, Tom Ross, Jacqui Smith, Anthea Tinker, Christina Victor, Alan Walker and representatives of the UK government funding departments.

Finally, the study would not be possible without the support of funders to the study. Funding for the first six waves of ELSA has been provided by the US National Institute on Aging, under the stewardship of Richard Suzman, and several UK government departments. The departments that contributed to wave 6 included the Department for Communities and Local Government, Department of Health, Department for Transport, Department for Work and Pensions, and the Office for National Statistics. The UK government funding has been coordinated by the Office for National Statistics and we are grateful for its role in the development of the study. We are particularly grateful to Valerie Christian, Rachel Conner, Tom Gerlach, Richard Goulsbra, Jonathan Smetherham, Dawn Snape, Louise Taylor and James Umpleby, all of whom have made valuable contributions to ELSA over this period. Members of the UK funding departments provided helpful comments on drafts of this report, but the views expressed in this report are those of the authors and do not necessarily reflect those of the funding organisations.

## 2. Inheritances, gifts and the distribution of wealth

Rowena Crawford *Institute for Fiscal Studies*

In wave 6, the ELSA survey included recall questions on the lifetime receipt of inheritances and substantial gifts (defined as those worth over £1,000 in today's money). This means that, for the first time, we have data on the lifetime receipt of inheritances and gifts, alongside detailed wealth statistics, for a large sample of today's cohorts of older individuals. In this chapter, we use this new ELSA data to document the pattern of inheritances and gifts received by today's cohorts of older individuals and the impact these transfers may have had on the distribution of wealth for these cohorts.

The analysis in this chapter shows:

- Over a quarter (28.2%) of ELSA respondents born between 1920 and 1959 report having received one or more inheritances in the past.
  - About a fifth (21.8%) report having received an inheritance from a parent or parent-in-law, 5.2% report having received an inheritance from an uncle or aunt and 0.9% report having received an inheritance from a grandparent.
- Individuals in later cohorts are more likely to have received an inheritance.
  - For example, by age 49, 13.2% of those born in the 1950s had received an inheritance, compared with 10.8% of those born in the 1940s, 8.4% of those born in the 1930s and 6.5% of those born in the 1920s.
- There is considerable variation in the real value of inheritances received by individuals. The median total value of inheritances received is £34,540 (2013 prices), but 15% of individuals who have received inheritance(s) received less than £5,000 in total, while 10% of individuals have received more than £200,000 in total.
- Inheritances are more likely to have been received by women, those with higher levels of education, those with no children, those with higher levels of household income, those who are of white ethnicity and those whose parents died at older ages.
- Among those who received any inheritance, those with higher levels of education and those with higher levels of income have on average received larger inheritances.
- Less than a tenth (7.0%) of ELSA respondents born between 1920 and 1959 report having received one or more substantial gifts (worth more than £1,000 in today's money) in the past.
  - About a twentieth (4.5%) report having received a gift from a parent or parent-in-law, 1.0% report having received a gift from an uncle or aunt and 0.3% report having received a gift from a grandparent.

- Individuals in later cohorts are more likely to have received a substantial gift: 8.7% among those born in the 1950s report having received such a gift, compared with 4.6% of those born in the 1920s.
- There is considerable variation in the real value of gifts received. The median total value of gifts received among those who have received at least one gift is £7,567 (2013 prices), but nearly 25% of individuals report having received less than £2,000 in total and over 5% report having received gifts totalling in excess of £100,000.
- Women and those with higher levels of education are more likely to have received substantial gifts in the past than men and those with lower levels of education.
- Among those who have received any substantial gifts, those of white ethnicity on average received larger gifts than those of non-white ethnicity.
- Inheritances and gifts are more likely to have been received by households higher up the wealth distribution. For example, individuals in the top 10% of the wealth distribution (conditional on positive wealth) are more than three times as likely to be in a household that has received an inheritance as individuals in the bottom 10%.
- Assuming inheritances and gifts have been saved since they were received and have accrued a real return of 3% a year, taken together they would be responsible for 11.5% of current household wealth holdings among these cohorts.
- Inheritances and gifts are worth more in absolute terms for individuals higher up the wealth distribution. However, the proportionate contribution of such transfers to wealth is greater among those towards the bottom of the wealth distribution, and so transfers are relatively more important for these individuals.
- Consequently, the direct impact of inheritances and substantial gifts is estimated to be a small equalising effect on the distribution of wealth among individuals born between 1920 and 1959.
- This finding is robust to alternative assumptions over the interest rate received on transfers and the proportion of transfers saved, when the same assumptions are applied to all individuals. When the interest rate received or the proportion of transfers saved is assumed to vary with wealth, the effects are more complex, but the scenarios considered in this chapter still suggest that transfers, if anything, have a small equalising direct impact on the distribution of wealth.

Having established these patterns of inheritances and gifts for today's older individuals, the important question for future research will be how these trends might differ for later cohorts.

## **2.1 Introduction**

Intergenerational transfers are an increasingly important public policy issue. Recent research comparing the economic experience of successive cohorts

found that individuals born in the 1960s and 1970s are likely to need inherited wealth if they are to be any better off in retirement than their predecessors (Hood and Joyce, 2013). Such a finding has resulted in two different concerns: first, that the inheritances expected by later cohorts may not come to pass, leaving them with lower standards of living in retirement than their predecessors; alternatively, that inheritances will play a major role in the financial circumstances of later cohorts, but that such intergenerational transfers would reinforce, and potentially widen, economic and social inequalities among these cohorts.

In addition to these concerns, intergenerational transfers are a key determinant of the intergenerational incidence of many different economic and social policies. For example, policies pertaining to pensions, social care, housing, childcare or higher education can all have knock-on consequences on cohorts other than those directly affected by the policy, through their impact on individuals' ability to leave an inheritance or individuals' need to receive one. Understanding these spillover effects is crucial for discerning the full impact of policies.

Despite this clear policy interest in understanding the pattern of intergenerational transfers, UK evidence on this topic was, until relatively recently, somewhat limited. For many years, the only data available on inheritances were those derived either from estate data, or from mortality and wealth ownership data. From such data, it is possible to estimate long-run trends in the overall flow of inheritances (see, for example, Atkinson (2013)), but since these data contain no information on the recipients of inheritances, it is not possible to say anything more detailed about how inheritances are distributed. However, more recently, surveys have been used to collect data on inheritances *received* by samples of individuals, which has started to improve our understanding of the relative importance of inheritances and their impact on the distribution of wealth.

The most comprehensive set of analysis on this topic is that summarised in Karagiannaki and Hills (2013). These authors use data from the British Household Panel Survey (BHPS) and Attitudes to Inheritance Survey (AIS) to address the question of how inheritances are distributed and what impact they have on the wealth distribution. However, there are important drawbacks to the data used. The AIS includes recall questions on lifetime receipt of inheritances and gifts, but has a small sample size and only limited data on other individual characteristics (importantly, the AIS does not contain good data on wealth levels). The BHPS is larger and contains a wider range of data, but only has data on the *flow* of inheritances and gifts received over the period since 1996. Since people in the BHPS will be at different stages of their lives, analysis of this flow of transfers is complicated by timing effects – many in the sample will already have received an inheritance that is not captured over that time frame, while others will expect to receive one in future. These drawbacks with the data lead the authors to caveat their findings and conclude that 'inheritance appears generally to maintain existing wealth inequalities rather than greatly changing them in either direction'.

In wave 6, the ELSA survey included recall questions on the lifetime receipt of inheritances and substantial gifts (defined as those worth over £1,000 in

today's money). This means that, for the first time, we have data on the lifetime receipt of inheritances and gifts, alongside detailed wealth statistics, for a large sample of today's cohort of older individuals.

In this chapter, we use these new ELSA data to document comprehensively the pattern of inheritances and large gifts received by today's cohorts of older individuals. Specifically, we investigate the size, timing and nature of inheritances and gifts received by those born between the 1920s and 1950s (inclusive) and illustrate the impact these transfers may have had on household wealth and the inequality of wealth holdings. This analysis goes beyond that presented in Karagiannaki and Hills (2013) in two important respects. First, we can distinguish differences that arise from individuals being at different stages in the life cycle from differences that arise even conditional on age – therefore we can analyse how patterns in inheritances have changed between cohorts. Second, we can be more confident in our analysis of the impact of inheritances and gifts on wealth and wealth inequality for these cohorts since we capture any transfers received over the lifetime and do not have to be concerned with how the timing of inheritances interacts with our window of analysis.

Since ELSA is a survey of older individuals, we must necessarily focus our analysis on those born in the 1950s and earlier. This has the disadvantage that much of the 'action' in terms of increasing prevalence of intergenerational transfers, or increasing 'need' for them, might be suspected to be among later cohorts – those who, for example, face greater costs associated with higher education or need larger deposits to get on the housing ladder, or have parents who are wealthier and therefore better placed to leave an inheritance. However, it is only once the impact of wealth transfers on these older cohorts is better understood that future research can start to consider how trends among later cohorts may differ and what impacts that may have.

The chapter proceeds as follows. Section 2.2 describes trends in the receipt of inheritances: how the prevalence of inheritances differs across cohorts, the distribution of amounts received, and the individual characteristics associated with receipt of inheritances. Section 2.3 presents similar analysis on trends in the receipt of substantial gifts, while Section 2.4 estimates the impact of these inheritances and gifts on wealth and wealth inequality. Section 2.5 concludes.

## **2.2 Trends in the receipt of inheritances**

### **2.2.1 The prevalence of inheritances**

Among ELSA wave 6 respondents born between 1920 and 1959, 28.2% reported having received an inheritance (excluding spousal inheritances) at some point in the past.<sup>1</sup> The majority of these individuals (78.7%) have received one inheritance, but some individuals (17.8%) have received two

---

<sup>1</sup> All the figures reported in this chapter exclude transfers (inheritances or gifts) received from a spouse or partner on the basis that such transfers are more likely to reflect a relabelling of what were in effect joint resources, rather than a true movement of resources.

inheritances and a small number (3.6%) have received three or more inheritances.<sup>2</sup>

This proportion of individuals reporting having received an inheritance is lower than was the case among similarly-aged individuals interviewed in the 2004 Attitudes to Inheritance Survey. In the AIS, 47.5% of those aged 45–54 and 49.3% of those aged 55–64 reported having personally received an inheritance in the past (see table 6 of Karagiannaki (2011a)). One potential concern with the ELSA data is that, for couples who keep their finances together, the questions on lifetime receipt of inheritances are only asked of one respondent (on behalf of both individuals) rather than of each individual separately. This could lead to an understatement of inheritances if the responding partner is not aware of inheritances that have been received by their spouse (which could have been received before they were a couple). However, this concern is mitigated by the fact that 90% of those in joint-finance couples answered the ELSA survey concurrently and so both partners were likely present in the room at the time the questions on inheritances (and gifts) were answered. The greater concern perhaps lies with the AIS. The ELSA sample in this age range is around ten times the size of the AIS sample, and has much greater claim to be representative of the household population. In particular, the AIS suffered from problems of low response; one reason for this suggested by the survey agency (MORI) was that ‘in less affluent areas, where people may have nothing to leave and no one to leave them anything, the survey was considered irrelevant by some’ (page 84 of Rowlingson and McKay (2005)). This sort of non-response bias could lead to a higher prevalence of inheritance in the AIS sample than among a more representative sample.

Table 2.1 illustrates the proportion of individuals in ELSA who reported having received an inheritance from various sources. Parents and parents-in-law are the most common source of inheritances: 21.8% of individuals report having received an inheritance from their parents or parents-in-law (77.4% of those who had received any inheritance(s)). The next most common source is uncles and aunts – from whom 5.2% report having received an inheritance – followed by siblings or partner’s siblings. Among these older individuals, relatively few report having received an inheritance from their grandparents (fewer than 1%).

Table 2.1 also illustrates how the prevalence of inheritances differs between cohorts. We need to be cautious with comparisons between cohorts for three reasons. First, older individuals may be less able to remember receiving inheritances in the past, and this recall bias could mean that the figures presented for the older cohorts understate the actual prevalence of inheritances. Second, differential mortality could mean that those born in older cohorts who have survived long enough to respond to ELSA in 2012–13 are not representative of all those born in the cohort in terms of their inheritance experience – this could lead us to overstate or understate the prevalence of

---

<sup>2</sup> Given that few individuals report receiving three or more inheritances, little information is lost by the constraint in the ELSA survey that information is only solicited on up to the three most important inheritances.

inheritance among the cohort, depending on whether those who die younger are less or more likely to have received an inheritance than those who survived to 2012–13. The evidence presented in Section 2.2.4 indicates that inheritances are more likely to be received by those with high education and higher income – given these characteristics are also positively correlated with chances of survival to older ages, it seems likely that analysis based on those who survive to 2012–13 will overstate the prevalence of inheritances across *all* those born in a certain cohort. Finally, since later cohorts are observed at younger ages, there may be timing effects that result in differences between the cohorts that would not still be apparent were all cohorts observed at the same age.

**Table 2.1. Receipt of inheritances, by cohort**

	Cohort				
	All	1920s	1930s	1940s	1950s
<b>% received an inheritance</b>	<b>28.2</b>	<b>21.9</b>	<b>29.8</b>	<b>34.0</b>	<b>24.0</b>
<i>% of whom have received:</i>					
1 inheritance	78.7	78.4	77.1	77.7	80.8
2 inheritances	17.8	14.7	18.7	19.0	16.3
3 or more inheritances	3.6	6.9	4.1	3.2	3.0
<b>% received an inheritance from:</b>					
Grandparent	0.9	0.4	0.5	0.6	1.6
Parent or parent-in-law	21.8	13.0	21.6	28.5	18.4
Uncle/Aunt	5.2	5.0	5.7	6.0	4.3
Sibling or partner's sibling	1.2	3.0	2.1	1.1	0.4
Child	0.1	0.1	0.0	0.1	0.0
Other	3.0	3.8	4.7	2.9	2.1
<i>Unweighted N</i>	<i>8,765</i>	<i>754</i>	<i>2,087</i>	<i>3,247</i>	<i>2,677</i>
<i>Memo: age in 2012–13</i>	<i>52–93</i>	<i>82–93</i>	<i>72–83</i>	<i>62–73</i>	<i>52–63</i>

Note: Figures for ‘% received an inheritance from’ do not sum to ‘% received an inheritance’ since some individuals have received inheritances from more than one type of donor.

These concerns notwithstanding, the figures presented in Table 2.1 suggest that there is an increasing prevalence of inheritance among later cohorts. Focusing on inheritances from parents, 28.5% of those born in the 1940s report having received a parental inheritance, compared with 21.6% of those born in the 1930s and 13.0% of those born in the 1920s. These comparisons are relatively unaffected by timing effects, since only 14% of the 1940s cohort, and virtually none of the 1920s and 1930s cohorts, have any living parents in 2012–13 from whom they could expect to receive an inheritance in future. While fewer (18.4%) of the 1950s cohort have received a parental inheritance by 2012–13, around half of this cohort still have at least one living parent and therefore the ultimate prevalence of parental inheritances among this cohort would be expected to be significantly higher. Among those with no living parents, 31.4% of the 1950s cohort have received an inheritance from their parents – the same as the proportion of the 1940s cohort (and greater than the 21.7% of the 1930s cohort and the 13.0% of the 1920s cohort).<sup>3</sup>

<sup>3</sup> While the proportion of those with no living parents who have received a parental inheritance is currently no higher among the 1950s cohort than among the 1940s cohort, this

Comparisons of inheritances from grandparents between cohorts are also unlikely to be distorted by timing effects, since few individuals in these cohorts will have living grandparents. Again the prevalence of inheritances from grandparents is higher among later cohorts – 1.6% among the 1950s cohort, compared with around 0.5% among the previous cohorts – but, on the whole, inheritances from grandparents are still relatively rare even among the later cohorts we consider.

The other notable difference between cohorts is the lower proportion of individuals in later cohorts reporting having received an inheritance from a sibling (or a sibling of their partner). Whether this is a true cohort effect, or the result of the siblings of individuals in later cohorts being more likely to still be alive, is unclear. However, if this were simply a timing effect, the future inheritances from siblings among later cohorts would act to reinforce the increasing overall prevalence of inheritances among later cohorts that is shown in Table 2.1.

***Taking into account expectations of future inheritances***

One way to circumnavigate any timing effects on the cohort comparisons is to take into account *expected* future inheritances in addition to inheritances that have been received by 2012–13. The ELSA survey asks respondents aged under 75 what their expected chance of receiving an inheritance in future is (and, for those who report a positive chance, what their expected chances of receiving an inheritance of greater than £10,000 and than £100,000 are).

Table 2.2 describes how these expectations differ across individuals in different cohorts. Over a quarter (28.2%) of individuals in the 1950s cohort report that there is more than a 50:50 chance that they will receive an inheritance in the future. This compares with 12.7% of the 1940s cohort and just 3.4% of those in the 1930s cohort who are still aged under 75.

**Table 2.2. Expectations of receiving an inheritance in future**

	Percentage reporting expected chance of receiving an inheritance in future:		
	Greater than zero	Greater than 50:50	80% or greater
<b>1950s</b>	<b>59.1%</b>	<b>28.2%</b>	<b>14.6%</b>
No living parents	37.8%	11.4%	8.0%
Has living parents	79.9%	44.7%	32.6%
<b>1940s</b>	<b>34.6%</b>	<b>12.7%</b>	<b>9.5%</b>
No living parents	28.6%	7.0%	5.1%
Has living parents	74.2%	50.3%	38.4%
<b>1930s<sup>a</sup></b>	<b>23.4%</b>	<b>3.4%</b>	<b>3.2%</b>

<sup>a</sup> The questions on expected receipt of inheritance are only asked of those (non-proxy respondents) aged under 75, and so only around one-quarter of the 1930s cohort were asked these questions. Virtually all of those in the 1930s cohort have no living parents.

might be expected to change over time. The timing of parental death is non-random, and if parents who die later are wealthier and more likely to leave an inheritance, then the proportion of the 1950s cohort who receive a parental inheritance is likely to end up higher than the proportion of the 1940s cohort.

Among individuals who have at least one parent still alive, the proportion reporting a greater than 50:50 chance of inheritance in future is particularly high: 44.7% of those in the 1950s cohort and 50.3% of those in the 1940s cohort. However, it is interesting to note that, even among those with no living parents, there are individuals who have high expectations of receiving an inheritance in future. This could suggest that some of the cohort differences in non-parental inheritances described in Table 2.1 could be the result of timing effects rather than true long-run cohort differences.

If we were to assume that all those who report an 80% or greater chance of an inheritance in future were to receive one (and that only these individuals were to do so), then the proportion of the 1950s cohort receiving an inheritance at some point during their lifetime would increase from 24.0% (in Table 2.1) to 39.6%. Similarly, prevalence among the 1940s cohort would increase from 34.0% to 40.2% and among the 1930s cohort from 29.8% to 30.3%.<sup>4</sup> If instead we were to assume that all those who report a greater than 50:50 chance of an inheritance were to receive one (and that only these individuals were to do so), the prevalence of inheritances would increase to 30.4% among the 1930s cohort, 42.3% among the 1940s cohort and 45.3% among the 1950s cohort.

Taken together, the evidence presented in Tables 2.1 and 2.2 strongly suggests an increase in the prevalence of inheritances among later cohorts.

### **2.2.2 The timing of inheritances**

The age at which inheritances were received by ELSA respondents is illustrated in Figure 2.1. Receipt of inheritance initially increases with age – for example, among the 1920s cohort, 1.6% of individuals reported receiving an inheritance in their 30s compared with 4.1% in their 40s and 6.4% in their 50s – but at older ages the probability of receipt declines, as the donors (typically parents) are more likely to have already died and passed on their wealth. Figure 2.1 suggests that the peak age for inheritance receipt is later among later cohorts – a fact that could be explained by rising life expectancies.

The proportion of individuals who received an inheritance in a given age bracket is almost always higher among later cohorts. The impact of this on the cumulative proportion of the cohort who have received an inheritance by a given age is illustrated in Figure 2.2.

Comparing the receipt of inheritances *by a given age* between cohorts is another way to avoid timing effects confounding cohort comparisons (under the assumption that the timing of inheritances is the same across cohorts). For example, by age 49, 13.2% of those born in the 1950s had received an inheritance compared with 10.8% of those born in the 1940s, 8.4% of those born in the 1930s and 6.5% of those born in the 1920s. The timing of inheritances may differ between cohorts but, if anything, increasing life

---

<sup>4</sup> These simulated future prevalence rates are lower than the sum of the proportion who have received an inheritance and the proportion who have an expected chance of inheritance of 80% or greater, since some of those who expect to receive an inheritance in future have also already received an inheritance in the past.

**Figure 2.1. Receipt of inheritances at each age, by cohort**

**Figure 2.2. Cumulative receipt of inheritances, by cohort**

expectancies would be expected to shift the timing of inheritances later among later cohorts. Therefore again the evidence strongly suggests an increase in the prevalence of inheritances among later cohorts.

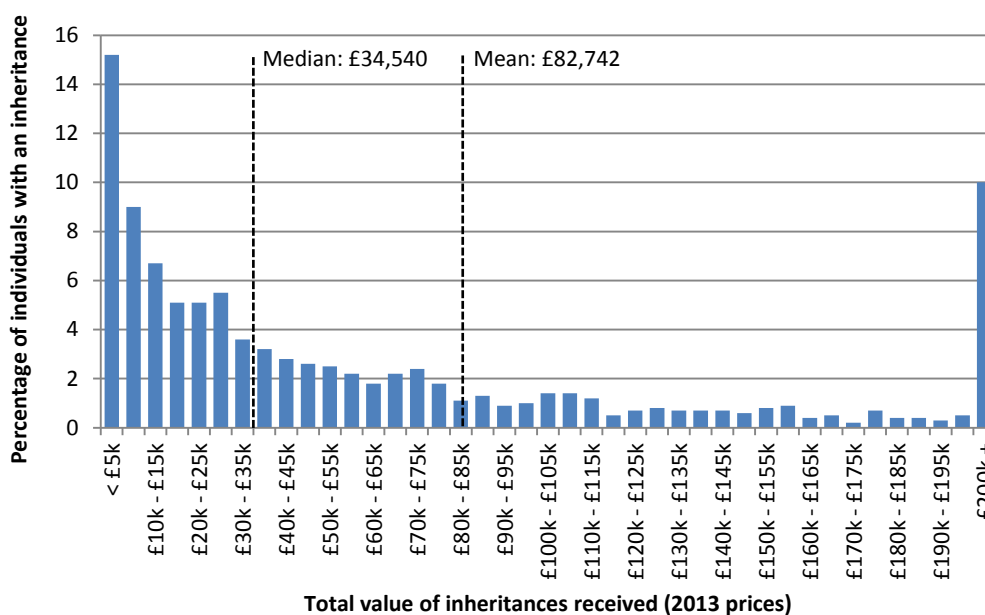

### **2.2.3 The value of inheritances received**

Not only do some individuals receive inheritances and others not, but the real value of inheritances received also varies considerably.<sup>5</sup> Figure 2.3 illustrates

<sup>5</sup> The real value of an inheritance is calculated by applying price inflation from the point of receipt until 2013. We use the retail price index (RPI) as the measure of price inflation since,

**Figure 2.3. Distribution of total real value of inheritance(s) received**

the distribution of the total value of inheritances received by each individual (for those who receive any inheritance). The median inheritance is around £34,500 (in 2013 prices),<sup>6</sup> but while a large proportion of individuals (15%) received less than £5,000 (in 2013 prices), 10% of individuals who received any inheritance received over £200,000 in total.

An alternative way to illustrate the inequality in the value of inheritances received is to use a Lorenz curve. This orders individuals according to the size of their inheritance, and plots the share of the total value of all inheritances received by each share of inheritors. If all individuals received the same inheritance, then the bottom 10% of inheritors would receive 10% of the total value of all inheritances, the bottom 20% would receive 20% of the total value and so on – in other words, the Lorenz curve would lie along the 45-degree line. The further the Lorenz curve lies from the 45-degree line, the greater inequality there is. Figure 2.4 illustrates that there is considerable inequality in the value of inheritances received. The bottom 20% of inheritors received less than 1% of the total value of inheritances received by all individuals, while the top 1% of inheritors received 13% of the total and the top 10% of inheritors received nearly 50% of the total. The Gini coefficient (which is a measure of the distance of the Lorenz curve from the 45-degree line) is 0.656, where a value of 0 would represent perfect equality in inheritances and a value of 1 would indicate maximal inequality (i.e. one individual received all the inheritances). The Gini coefficient for the value of inheritances across *all*

---

while this index is now not considered to be a good indicator of changes in the cost of living (specifically, it is widely believed to overestimate inflation), it is the only price index available on a sufficiently long-run basis for our analysis.

<sup>6</sup> It is interesting to note that this is higher than the median inheritance reported in the AIS, which was around £15,200 among those aged 45–54 in 2004 and £20,100 among those aged 55–64. (Based on figures in table 6 of Karagiannaki (2011a) but converted into 2013 prices for comparability with ELSA figures.)

individuals, where those who have not received an inheritance are counted with a value of £0, is 0.903.<sup>7</sup>

The considerable variation in the value of inheritances received is not driven solely by the source of the inheritance. On average, parental inheritances are larger than inheritances from sources other than parents – for example, the median total value of parental inheritance(s) among those who received one is

**Figure 2.4. Inequality in the value of inheritance(s) received**

**Table 2.3. Value of inheritance(s) received, by donor**

	All	By donor:	
		Parental	Non-parental
<b>Average value (among recipients)</b>			
Median	£34,540	£37,805	£19,792
Mean	£82,742	£77,325	£64,737
<b>Percentage of recipients who received:</b>			
Less than £5,000	15.1%	13.4%	24.5%
£5,000 to £20,000	20.7%	20.8%	26.1%
£20,000 to £50,000	22.6%	23.4%	21.1%
£50,000 to £200,000	31.1%	33.9%	21.7%
£200k or more	10.4%	8.4%	6.8%
<b>Inequality</b>			
Gini coefficient	0.656	0.622	0.733
<i>Unweighted N</i>	<i>2,760</i>	<i>2,156</i>	<i>984</i>

Note: Figures relate to the total value of inheritances received from any given donor type, among those who receive any inheritance from that donor type. The sample size for ‘all’ is less than the sum of the sample sizes for ‘parental’ and ‘non-parental’ since some individuals have received both parental and non-parental inheritances.

<sup>7</sup> For comparison, the Gini coefficient for annual incomes across the UK population is estimated to have been 0.34 in 2012–13 (Belfield et al., 2014).

£37,805, compared with £19,792 for the total value of non-parental inheritances among those who received a non-parental inheritance – but there is a wide distribution of values for both categories of inheritance. As set out in Table 2.3, 13.4% of individuals who received any parental inheritance(s) received less than £5,000 in total, while 8.4% received £200,000 or more. Among those who received a non-parental inheritance, 24.5% received less than £5,000 in total from these inheritances, while 6.8% received £200,000 or more. Parental inheritances are somewhat more equally distributed among recipients than non-parental inheritances – with a Gini of 0.622 compared with 0.733 – but both are very unequally distributed.

#### **2.2.4 Characteristics associated with receipt of inheritances**

In order to begin to understand the implications of inheritances for the transmission of wealth and the intergenerational incidence of economic and social policies, it is necessary to explore not just the overall prevalence of inheritances, but also *who* receives inheritances and what characteristics are associated with the value of inheritances received.

The proportion of individuals with different characteristics who have received inheritances, and the average amounts they received, are described in Table 2A.1 in the appendix to this chapter. However, since these different characteristics are related, we instead focus on the association of each characteristic with inheritance *controlling for* other characteristics using multivariate regression analysis. The results from a probit regression exploring the characteristics associated with the probability of receiving an inheritance are shown in the first column of Table 2.4, while the results of regression analysis exploring the characteristics associated with the value of total inheritance are shown in the second column. The equivalent analyses for parental inheritances only and non-parental inheritances only are provided in Tables 2A.2 and 2A.3, respectively.

Consistent with the patterns described in Section 2.2.1, individuals in later cohorts are found to be more likely to have received an inheritance even after controlling for a number of individual characteristics. This is driven by a greater likelihood of having received a parental inheritance; individuals in later cohorts are actually found to be less likely to have received a non-parental inheritance. However, conditional on receipt of an inheritance, there is no difference in the average real value between individuals in different cohorts.

Sex and ethnicity also both affect the probability of receipt but not the real value conditional on receipt. Women are 6 percentage points more likely to have received an inheritance than men, while non-white individuals are 35 percentage points less likely to have received an inheritance than white individuals. These associations hold (qualitatively) for both parental inheritances and non-parental inheritances.

A number of other individual characteristics are associated with both the probability of receiving an inheritance and the value of an inheritance. For example, those with higher levels of education and those with higher incomes are both more likely to report having received an inheritance, and to have on

Note: Figures in the first column are derived marginal effects from a probit regression; the first figure in the first column indicates that those born in the 1930s are 6.7 percentage points more likely to have received an inheritance than those born in the 1920s. Figures in the second column are derived marginal effects from a regression of log(value) for those who reported having received at least one inheritance; the first figure in the second column indicates that, among those who had received any inheritance, those born in the 1930s on average received 5.9% less than those born in the 1920s. \*\*\*/\*\*/\* indicates a statistically significant difference from the reference category at the 1%/5%/10% level. We do not report standard errors directly as they are not in the same metric as the reported derived marginal effects.

average received a larger inheritance, than those with lower levels of education and those with lower incomes. Again this holds true for both parental and non-parental inheritances.

Interestingly, those with children are less likely to have received an inheritance. The additional results presented in the appendix show that this arises from a lower probability of having received a non-parental inheritance, rather than a lower probability of having received a parental inheritance. However, having children is also associated with a lower value of inheritance among those who have received one, and that is driven by a lower value of both parental inheritances and non-parental inheritances. These patterns would be consistent with individuals dividing their bequeathed wealth between both their children and their grandchildren (rather than, say, leaving all their wealth to their children or all their wealth to their grandchildren).

Finally, one potentially important factor for the prevalence and/or value of inheritances is the age of an individual's parents when they died. We could think of this being associated with parental inheritances for two reasons. First, if wealthier individuals live for longer, then those dying at older ages are those who have been wealthier over their lifetimes and therefore they might be more likely to have wealth (or more wealth) to bequeath. On the other hand, if individuals live for longer, they have a longer retirement to finance and so they may use up more of their wealth and be less likely (or have less) to bequeath. The results in Table 2.4 illustrate that those whose parents died at older ages are more likely to have received an inheritance. For example, those whose last parent died between ages 80 and 90 are 6 percentage points more likely to have received an inheritance than those whose parents died between ages 70 and 80. This suggests that the effect of differential mortality on the probability of inheritance is stronger than the impact of greater decumulation. However, it is interesting to note that, conditional on receipt, having a parent who died at an older age does not appear to have a significant impact on the total value of inheritance(s) received.<sup>8</sup>

#### ***The interaction between parental and non-parental inheritances***

An interesting question is whether those individuals who receive an inheritance from their parents are more likely to also receive an inheritance from someone other than their parents, and whether the values of parental and non-parental inheritances are correlated for those who receive both.

The regression results presented in Tables 2A.2 and 2A.3 suggest that those who have received a parental inheritance are 6 percentage points more likely to receive a non-parental inheritance than those who have not (after controlling for other individual characteristics), while those who have received a non-parental inheritance are 11 percentage points more likely to receive a parental inheritance. Furthermore, among those who receive both an inheritance from their parents and a non-parental inheritance, the total values received are also

---

<sup>8</sup> The stars in Table 2.4 indicate a statistically significant difference from the reference category (that at least one parent is still alive). Additional significance tests indicate that the average value does not differ significantly depending on the age at which the last parent died (i.e. the coefficient for 'last died before age 60' from the regression of  $\log(\text{value})$  is not statistically significantly different from the coefficient for 'last died after age 90').

somewhat positively correlated, with a correlation coefficient of 0.41. However, the overall correlation across all individuals (where those who have not received a certain type of inheritance are counted as having received £0) is relatively weak, with a correlation coefficient of just 0.16.

### ***Correlation in receipt of inheritances within households***

There is also correlation in the receipt of inheritances within couples. Among coupled respondents who had received an inheritance, 46.7% had a partner who had also received an inheritance, compared with 17.9% of coupled respondents who had not themselves received an inheritance.<sup>9</sup> However, within couples where both individuals had received an inheritance, there is no correlation between the value of those inheritances (the correlation coefficient is just 0.08). Overall, when those with no inheritance are included with a value of £0, the correlation between the values of inheritances received by members of a couple is 0.12.

Since married individuals who have received inheritances are not all married to partners who have also received inheritances, the proportion of individuals in households that have benefited from inheritances is greater than the proportion of individuals who have themselves benefited from an inheritance: while 28.2% of individuals have received an inheritance, 36.8% of individuals are in households that have benefited from an inheritance.

## **2.3 Trends in the receipt of substantial gifts**

Intergenerational transfers happen not just on death but also throughout individuals' lives. These *inter-vivos* gifts can be important – both because, over a lifetime, they can amount to a significant sum and because, being an active choice of the donor, they are arguably more related to the 'need' of the recipient than are inheritances in terms of their timing and value.

There is also reason to believe that the prevalence and value of gifts are increasing – particularly among younger individuals in recent years. The increasing charges for higher education and the larger deposits now needed by those wanting to get on the housing ladder are two important drivers behind this trend. For example, research by the Council of Mortgage Lenders (2006 and 2011) has suggested the proportion of first-time buyers aged under 30 who receive assistance with their deposit increased from around 8% in 1995 to almost 50% in 2005, and to nearly 80% in 2011.

The ELSA survey asks individuals about their lifetime receipt of 'substantial' gifts – defined as a gift worth more than £1,000 in today's money. This is not the complete picture of *inter-vivos* transfers, since the data do not capture smaller gifts, regular financial support or probably many types of transfers in kind, but it is still an important addition to the overall picture of intergenerational transfers among these cohorts.

---

<sup>9</sup> Figures exclude joint inheritances.

### 2.3.1 The prevalence of gifts

Receipt of substantial gifts is much less common among ELSA respondents born between 1920 and 1959 than receipt of inheritances: only 7.0% of individuals have ever received such a gift.<sup>10</sup> The majority of individuals who have received a gift have only received one (78.9%), but 14.4% of recipients have received two gifts while 6.7% have received three or more gifts. As with inheritances, gifts are predominantly received from parents and, to a much lesser extent, uncles or aunts and grandparents.

**Table 2.5. Receipt of substantial gifts, by cohort**

	All	Cohort			
		1920s	1930s	1940s	1950s
<b>% received a gift</b>	<b>7.0</b>	<b>4.6</b>	<b>5.1</b>	<b>6.7</b>	<b>8.7</b>
<i>% of whom have received:</i>					
1 gift	78.9	86.0	85.4	81.4	74.6
2 gifts	14.4	11.3	10.5	10.9	18.1
3 or more gifts	6.7	2.7	4.0	7.7	7.3
<b>% received a gift from:</b>					
Grandparent	0.3	0.1	0.1	0.2	0.5
Parent or parent-in-law	4.5	2.2	2.2	4.4	6.2
Uncle/Aunt	1.0	0.7	1.0	1.0	1.0
Sibling or partner's sibling	0.3	0.4	0.3	0.5	0.2
Child	0.1	0.1	0.1	0.1	0.0
Other	1.0	1.1	1.7	0.7	0.9
<i>Unweighted N</i>	<i>8,765</i>	<i>754</i>	<i>2,087</i>	<i>3,247</i>	<i>2,677</i>
<i>Memo: age in 2012–13</i>	<i>52–93</i>	<i>82–93</i>	<i>72–83</i>	<i>62–73</i>	<i>52–63</i>

Note: Figures for ‘% received a gift from’ do not sum to ‘% received a gift’ since some individuals have received gifts from more than one type of donor.

Table 2.5 describes how the reported receipt of gifts differs across cohorts. Gifts appear to be much more prevalent among later cohorts: only around 5% of those born in the 1920s and 1930s report having received a substantial gift, compared with nearly 7% among the 1940s cohort and nearly 9% among the 1950s cohort. However, we may be more concerned about recall bias in the context of gifts than we were in the context of inheritances. First, receiving a gift – even a substantial one – is likely to be a less memorable occurrence than parental death and any consequent inheritance. Older individuals may therefore have forgotten that they received a gift in the past. Second, individuals may not realise that a gift they received a long time ago would count as a ‘substantial’ gift. The ELSA survey asks about gifts that are worth more than £1,000 in today’s money – if received in 1970, a gift would only need to have been around £75 when received to meet that criterion. However,

<sup>10</sup> As with receipt of inheritances, this figure looks low relative to that which might be expected based on the AIS data, although directly comparable figures are not available. A tenth (10%) of individuals in ELSA born between 1920 and 1959 report that they or their partner had ever received a gift worth more than £1,000 in 2012–13 money, compared with 34.7% of those aged 45–54 (20.4% of those aged 55–64) in the AIS reporting they or their spouse had received a transfer worth £500 or more in 2004 prices (Karagiannaki, 2011b).

while we might ordinarily be concerned that individuals do not fully appreciate the effects of inflation over such long periods of time, the ELSA interviewers are provided with prompts (that £1,000 in today's money would be roughly £20 in the 1920s and 1930s, £30 in the 1940s, £45 in the 1950s, £65 in the 1960s, £130 in the 1970s, £400 in the 1980s and £650 in the 1990s). This should reduce the likelihood of gifts from longer ago being recalled but not reported. To the extent that recall bias does result in older individuals under-reporting gifts they have received though, the figures presented in Table 2.5 would overstate the increasing prevalence of substantial gifts among later cohorts.

### 2.3.2 The timing of gifts

Unlike inheritances, the timing of which is determined by the death of the donor, the timing of gifts one would suppose is more likely to be related to the needs of the recipient.<sup>11</sup> We might therefore expect gifts to be more prevalent early in working life – for example, associated with first marriages or setting up a home.

The actual timing of reported gifts is illustrated in Figure 2.5. Very few individuals report receiving a gift below the age of 20 (a pattern that perhaps might be suspected to be very different among later cohorts from among those we consider, given the increase in university attendance and the increase in

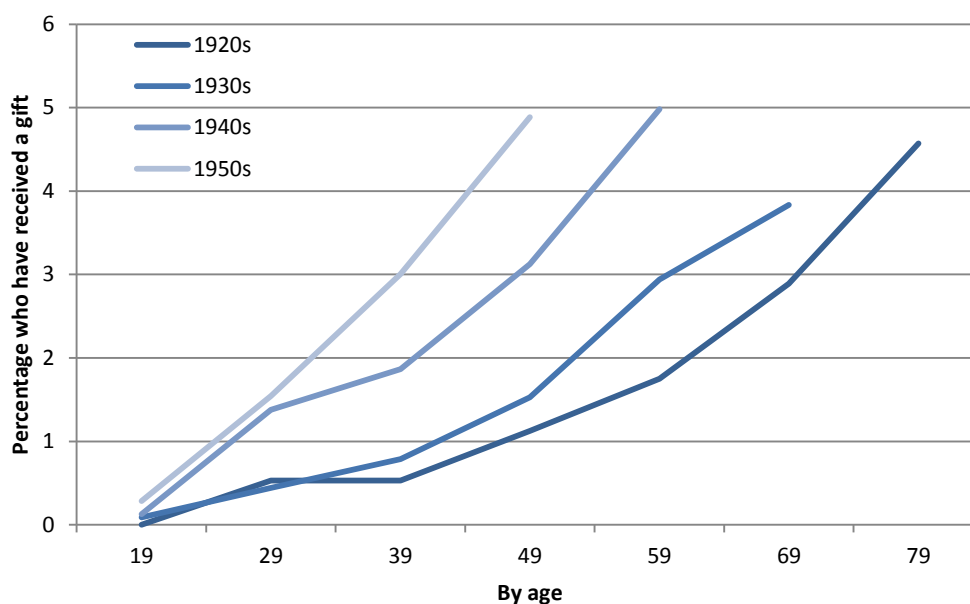

**Figure 2.5. Receipt of gifts at each age, by cohort**

<sup>11</sup> The timing of gifts may also be affected by the different tax treatment of inheritances and gifts. Under the current UK tax system, donors must pay inheritance tax of 40% on estates above a certain threshold (currently £325,000). Gifts made during life, however, are not taxed if they amount to less than £3,000 per year or if they are made more than 7 years before the death of the donor. Gifts of more than £3,000, which are made fewer than 7 years before the donor's death, would be added to the value of the donor's estate when assessing the liability of the donor for inheritance tax. Inheritances and gifts made to spouses are exempt from inheritance tax.

**Figure 2.6. Cumulative receipt of gifts, by cohort**

charges for attending university). Gifts are most likely to be received at older ages. In fact, more individuals report receiving a substantial gift in their 50s than report receiving one in any other 10-year age band.

This pattern could be the result of recall bias, if a greater proportion of gifts received in more recent years are reported in ELSA. Alternatively (or in addition), it could be indicative that a major motivation for gifts to these cohorts is simply to transfer wealth before death, rather than wait to pass on wealth as a bequest.

The cumulative proportion of each cohort who have received a substantial gift by a given age is illustrated in Figure 2.6. Concerns about recall bias aside, this would suggest that gifts are more prevalent among later cohorts: over four times as great a proportion of the 1950s cohort report having received a substantial gift by age 49 as among the 1920s cohort.

### **2.3.3 The value of gifts received**

The distribution of the total real value of gifts received by each individual (for those who receive one or more gifts) is illustrated in Figure 2.7.<sup>12</sup> There is considerable variation in the total value of gifts received: nearly a quarter of recipients report receiving less than £2,000 in total (in 2013 prices), while 6.3% of recipients report receiving gifts totalling more than £100,000 each (in 2013 prices).

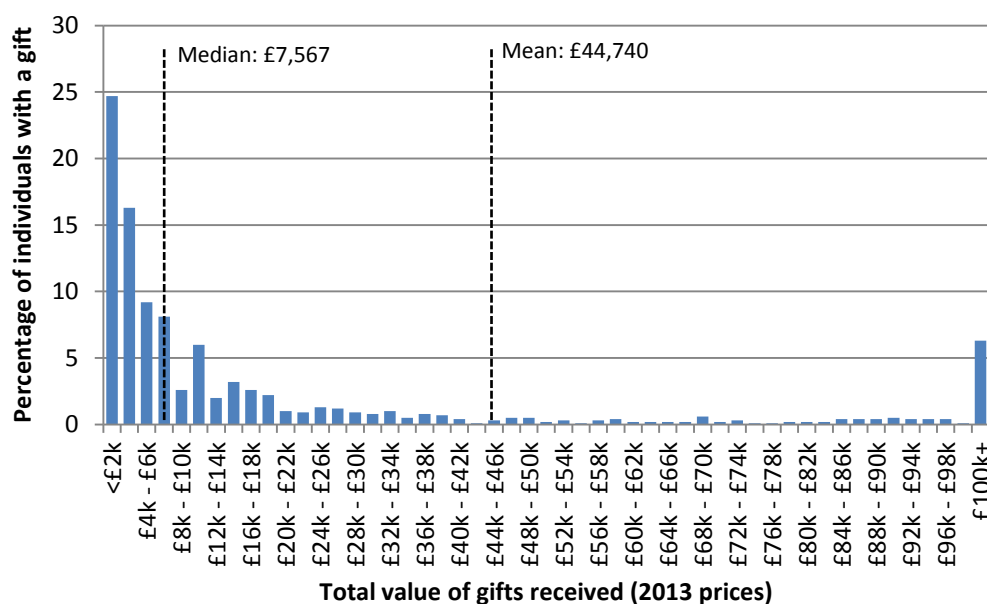

The Lorenz curve in Figure 2.8 illustrates how unequally gifts are distributed among those who receive them. The bottom 20% of gift recipients again

---

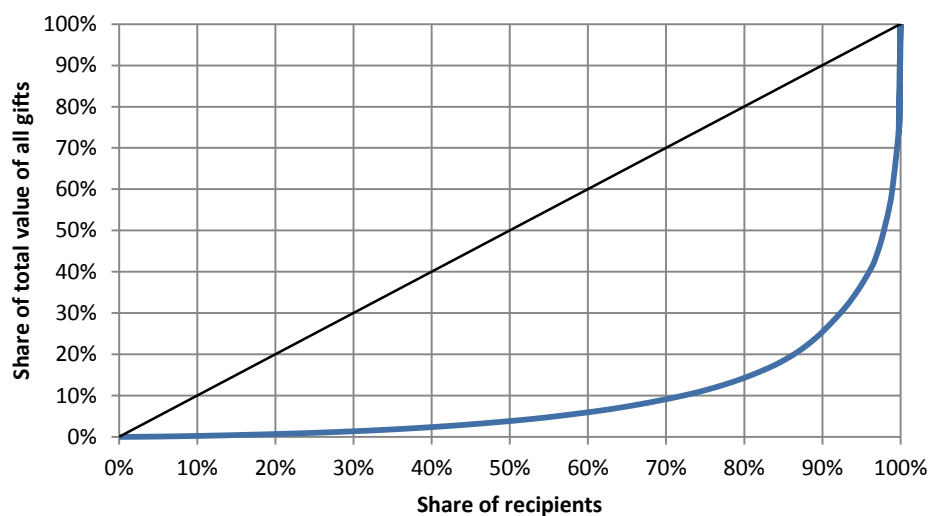

<sup>12</sup> The real value of a gift is calculated by applying price inflation from the point of receipt until 2013. We use the retail price index (RPI) as the measure of price inflation since, while this index is now not considered to be a good indicator of changes in the cost of living (specifically, it is widely believed to overestimate inflation), it is the only price index available on a sufficiently long-run basis for our analysis.

receive less than 1% of the total value of all gifts, but the top 1% receive 40% of the total and the top 10% receive 75% of the total. We cannot perfectly compare the inequality in the value of gifts received with the inequality in the value of inheritances received since, while we observe all inheritances, we only observe gifts of greater than £1,000 (in today's prices). However, the data available suggest that gifts are less equally distributed among recipients than inheritances; the Gini coefficient measuring inequality in the total value of gifts received is 0.820 (compared with 0.646 for inheritances among those who inherit more than £1,000). The Gini coefficient for the value of substantial gifts across *all* individuals, where those who have not received a gift worth more than £1,000 are counted with a value of £0, is 0.987.

**Figure 2.7. Distribution of total real value of gift(s) received**

**Figure 2.8. Inequality in the value of gift(s) received**

### 2.3.4 Characteristics associated with the receipt of gifts

The proportion of individuals with different characteristics who have received substantial gifts, and the average amounts they received, are described in Table 2A.4 in the appendix. However, as with the analysis of inheritances, here we focus on the results of multivariate analysis that aims to capture the association of each characteristic with gifts while holding all other characteristics constant. The results of a probit regression exploring the characteristics associated with the probability of receiving a substantial gift are shown in the first column of Table 2.6, while the results of regression analysis exploring the characteristics associated with the total value of gifts received are shown in the second column.

**Table 2.6. Individual characteristics associated with the probability of having received a gift, and the total value of gifts received**

	Association with probability of receipt	Association with mean value

<i>Sample size</i>	8,481	625

Note: Figures in the first column are derived marginal effects from a probit regression; the first figure in the first column indicates that those born in the 1930s are 0.6 percentage points more likely to have received a gift than those born in the 1920s. Figures in the second column are derived marginal effects from a regression of log(value) for those who reported having received at least one gift; the first figure in the second column indicates that, among those who had received any gift, those born in the 1930s on average received 37.9% less than those born in the 1920s. \*\*\*/\*\*/\* indicates a statistically significant difference from the reference category at the 1%/5%/10% level. We do not report standard errors directly as they are not in the same metric as the reported derived marginal effects.

The results suggest that individuals in later cohorts are more likely to have received a substantial gift – for example, those born in the 1950s are 4 percentage points more likely to have received a gift than those born in the 1920s. However, conditional on receipt, those in later cohorts on average receive gifts of a lower value. While this could be indicative of cohort differences in the prevalence and size of gifts, it is also the pattern that would arise from older respondents having greater difficulty recalling gifts received, and in particular smaller gifts received, than younger respondents.

Those with higher levels of education are more likely to have received a gift than those with lower levels of education. Women are more likely to have received a substantial gift in the past than men but, conditional on receipt, the average value received by women is if anything lower than that received by men. Ethnicity is not strongly associated with the prevalence of gifts, but among those who have received a gift, the average value received by non-white individuals is 62% lower than the average value received by white individuals.

### ***Correlation in receipt of gifts within households***

As with inheritances, there is also correlation in the receipt of gifts within couples. Among coupled respondents who had received a substantial gift, 13.1% had a partner who had also received a substantial gift, compared with 4.4% of coupled respondents who had not themselves received such a gift.<sup>13</sup> However, within couples where both individuals had received a substantial gift, there is no correlation between the value of those gifts (the correlation coefficient is just 0.09). Overall, when those who have not received any substantial gifts are included with a value of £0, the correlation between the values of gifts received by members of a couple is 0.11.

Since married individuals who have received a substantial gift are not all married to partners who have also received a gift, the proportion of individuals in households that have benefited from substantial gifts is greater than the proportion of individuals who have themselves benefited from such a gift: while 7.0% of individuals have received a substantial gift, 9.9% of individuals are in households that have benefited from a substantial gift.

### ***The interaction between gifts and inheritances***

An interesting question is whether those individuals who receive inheritances are also those who receive *inter-vivos* transfers. This is particularly important in the context of concern about the impact of intergenerational transfers on economic and social inequalities and mobility. If the same individuals receive both sorts of transfers, then considering only inheritances or only gifts could understate the impact of intergenerational transfers on inequality. On the other hand, if different individuals received inheritances and gifts, focusing only on one or the other could result in an overstatement of the impact of transfers on inequality.

In fact, the ELSA data suggest that there is only a very weak correlation between the receipt of inheritance and the receipt of gifts. Among those who

---

<sup>13</sup> Figures exclude joint gifts.

report having received an inheritance in the past, 7.2% report having also received a gift, while 6.9% of those who report not having received an inheritance in the past report having received a gift. Similarly, among those who report having received a gift, 29.2% report having also received an inheritance, while 28.1% of those who report not having received any gifts report having received an inheritance. Among those who report having received both inheritance(s) and gift(s), the correlation between the total real value received from each is just 0.15. Across the whole sample, where individuals who have not received an inheritance or gift are counted as having received £0, the correlation between the total value of inheritances received and the total value of gifts received is 0.01.

A full understanding of the impact of intergenerational transfers on individual circumstances therefore requires careful consideration of both inheritances and *inter-vivos* transfers. For the cohorts considered in this chapter (those born in the 1920s to 1950s), the former are the more important, being more prevalent and of greater value on average, but the same may not necessarily be true of future cohorts.

## **2.4 The contribution of inheritances and gifts to wealth and wealth inequality**

How then have these inheritances and gifts received by the 1920s to 1950s cohorts affected the distribution of wealth and wealth inequality? This is a crucial question for understanding the impact of intergenerational transfers on economic and social inequalities and mobility. Unfortunately, it is a difficult question to answer, not least because we do not know how much wealth individuals had when they received their inheritance or gift, or what they did with the transfer. However, since we observe individuals' current household wealth holdings, we can, under some assumptions, describe the contribution of inheritances and gifts to current wealth. We start in Section 2.4.1 by briefly describing the distribution and composition of wealth among individuals born between 1920 and 1959. In Section 2.4.2, we discuss the issues involved in measuring the contribution of transfers to current wealth. We then present our estimates of the contribution of inheritances and gifts to wealth in Section 2.4.3 and discuss the impact on wealth inequality in Section 2.4.4.

When considering wealth, it often makes more sense to focus on households rather than individuals. Many couples hold assets jointly, and even when assets are notionally held by different individuals in a couple, this may not be truly individual wealth but may be implicitly (or explicitly) pooled within the household. In contrast to the analysis presented in Sections 2.2 and 2.3, we therefore now focus on the impact of receipt of inheritances and/or gifts *by the household on household wealth*. Our unit of analysis is still individuals, but for couples we pool and share equally between individuals both transfers received and current levels of wealth – we refer to this as household wealth per person.<sup>14</sup>

---

<sup>14</sup> Our main results are not sensitive to this choice of equalisation factor for couples or to the exclusion of couples from the sample.

### 2.4.1 The distribution and composition of current wealth

The measure of current household wealth we consider consists of financial wealth, primary housing wealth, other property wealth and physical wealth (which includes business wealth, farms, land, trusts, collectibles and antiques). Among our sample of individuals born between the 1920s and 1950s (inclusive), mean household wealth is £202,824 per person, while median household wealth is somewhat lower at £132,103 per person. The majority of our sample have positive net wealth, but 6% have zero or negative net wealth.

Table 2.7 describes the average holding of each of the main types of wealth. The largest component is net primary housing; 80% of individuals are in households that own primary housing wealth, and median housing wealth is £100,000 per person. Primary housing wealth is more equally distributed across individuals than total net wealth – with a Gini coefficient of 0.495 compared with 0.569 – and is much more equally distributed than other housing wealth and physical wealth, which are held by relatively few individuals. Most individuals are in households with positive net financial wealth, but this is relatively unequally distributed (Gini coefficient 0.772). Median net financial wealth is £12,600, while mean net financial wealth is £47,522.

**Table 2.7. Composition of current net wealth**

	Mean	Median	Percentage with positive wealth	Gini coefficient
<b>Total net wealth</b>	<b>£202,824</b>	<b>£132,103</b>	<b>94%</b>	<b>0.569</b>
<i>of which:</i>				
Net financial	£47,522	£12,600	87%	0.772
Net primary housing	£121,114	£100,000	80%	0.495
Net other housing	£14,029	£0	13%	0.945
Physical	£20,160	£0	14%	0.981

### 2.4.2 How to measure the contribution of transfers to wealth

Wealth at a given age is determined by an individual's history of earnings, savings rates, rates of return and transfers. This is illustrated by equation 1, where  $W_t$  is current wealth,  $E_k$  is earnings in period  $k$ ,  $C_k$  is consumption in period  $k$ ,  $T_k$  are transfers received in period  $k$  and  $r$  is the rate of return.

$$[1] \quad W_t = \sum_{k=1}^t (E_k + T_k - C_k) \prod_{j=k+1}^t (1 + r_j)$$

This accounting identity is uncontroversial, but it does not disentangle the contribution of transfers to wealth. Doing so requires us to know how much of a transfer has been consumed and how the transfer has been capitalised over time. For example, if the transfer was spent on a consumption good that the individual would not have purchased in the absence of the transfer, then the impact on current wealth is zero<sup>15</sup> (i.e. the transfer  $T_k$  is just offset by higher

<sup>15</sup> This might, for example, be the case if an individual is credit constrained, and receipt of inheritance enables them to purchase a consumption good that they would not otherwise have the resources to purchase.

$C_k$ ). This represents a reasonable lower bound on the contribution of transfers to wealth. On the other hand, suppose the transfer is saved. The contribution of the transfer to current wealth could then be argued to be the initial transfer, capitalised at some rate of interest each year since the transfer was received – as set out in equation 2.

$$[2] \quad \text{Contribution of transfer to wealth} = T_k \prod_{j=k+1}^t (1 + r_j)$$

It would be convenient if we were able to think of this as an upper bound on the contribution of transfers to wealth, i.e. if some of the transfer is consumed, then the contribution to wealth would lie somewhere between zero and the value given by equation 2. However, the contribution of a transfer to current wealth holdings could be even greater than that suggested by equation 2 if an individual is able to use the transfer to access a higher rate of interest for their other wealth. For example, suppose an individual receives an inheritance and combines that with their own savings to buy a house. If the real rate of return on that property wealth is greater than the return they would otherwise have got on their savings, then the contribution of the inheritance to their current wealth is arguably not just the capitalised value of their inheritance, but that plus the greater capitalisation of their existing wealth.

For the purposes of the main analysis presented in this chapter, we assume that all inheritances and gifts are saved rather than consumed and that they accrue a time-constant real rate of interest of 3% per year from the point of receipt until 2013.<sup>16</sup> The contribution of each transfer to wealth is therefore that given by equation 3 (where  $T_k$  is the value of the transfer and  $k$  is the year in which it was received). For those who have received multiple transfers during their lifetimes, the total contribution of transfers to wealth will be the sum of these contributions.

$$[3] \quad \text{Assumed contribution of transfer to wealth} = T_k (1.03)^{(2013-k)}$$

In Section 2.4.4, we illustrate the sensitivity of our main results to the assumptions made about the interest rate and the proportion of transfers saved.

### **2.4.3 The contribution of transfers to current wealth**

As stated above, 36.8% of ELSA respondents born between 1920 and 1959 are in households that have received an inheritance. If we assume that inheritances are pooled within households and capitalised at a real rate of 3% per year, the average contribution of inheritances to household wealth per person among these individuals is £57,892. Across all individuals (i.e. counting those whose households have not received an inheritance as having received £0), the mean contribution of inheritances is £21,513. This is equivalent to 10.6% of average net private wealth holdings.

This figure of 10.6% is lower than previous estimates of the ratio of inherited wealth to marketable wealth: Karagiannaki (2011a) estimated a ratio of 28%

---

<sup>16</sup> A baseline rate of return of 3% is common in the international literature that has investigated the contribution of inheritances to wealth – see, for example, Klevmarken (2004) and Wolff and Gittleman (2013).

using the AIS data, and the Royal Commission on the Distribution of Income and Wealth (1977) suggested that the size of inherited wealth in 1973 was 20% of aggregate wealth. However, it is important to note that these statistics are defined for slightly different populations. The Karagiannaki figures and the Royal Commission figures are for the whole population, while the 10.6% figure calculated here is only for those born in the 1920s to 1950s. These older individuals have higher average wealth than the population as a whole (due to patterns of saving over the life cycle), and therefore the ratio of inheritances to total wealth for these cohorts specifically would be expected to be lower than the average for the population as a whole.

**Table 2.8. Contribution of inheritance(s) to current net wealth**

	% in households that have received an inheritance	Mean contribution of inheritances to household wealth per person (£, 2013)		Mean contribution of inheritances to wealth across all individuals
		Across all individuals	Across recipients only	
All	36.8%	21,513	57,892	10.6%
Net wealth ≤£0	14.5%	2,649	18,286	–
<i>Those with positive net wealth</i>				
Least wealthy	17.6%	2,967	15,961	108.7%
Decile 2	28.1%	7,578	26,930	21.7%

Most wealthy	55.7%	77,032	137,998	8.7%

Note: Wealth deciles are defined on the basis of net household wealth per person for those with positive net wealth. The contribution of inheritances to net wealth is calculated assuming they are capitalised at a real rate of 3% per year from the time of receipt. Unweighted N = 8,457.

Table 2.8 sets out how the prevalence of inheritances, and the contribution of inheritances to household wealth per person, vary across the current wealth distribution. Individuals in wealthier households are more likely to benefit from inheritances than individuals in less wealthy households – for example, among individuals in the bottom 10% of the distribution of net household wealth per person (conditional on having positive net wealth), 17.6% are in households that have received an inheritance, compared with 55.7% among the wealthiest 10% of individuals; in other words, individuals in the top wealth decile are more than three times as likely to be in a household that has received an inheritance than individuals in the bottom wealth decile. Similarly, individuals in wealthier households benefit from larger inheritances on average than individuals in less wealthy households. In part, this pattern would be expected mechanically, since if everyone had equal non-inherited wealth, those with the greatest inherited wealth would end up at the top of the wealth distribution. However, the differences in net wealth across the wealth deciles

are considerably greater than the differences in inheritances, implying that the value of inheritances is on average greater among those with greater non-inherited wealth.<sup>17</sup>

The proportionate contribution of inheritances to current net wealth is dealt with in the final column of Table 2.8. The figures in this column represent the ratio of the mean absolute contribution of inheritance (across all individuals in the group) to the mean value of current total net wealth – in other words, the proportion of the current wealth of the group that could be said to be due to inheritances received (under the assumptions described in Section 2.4.2). The crucial finding is that the relative contribution of inheritances to current net wealth is highest among individuals in the bottom 20% of the net wealth distribution and lowest amongst individuals in the top 10%. In other words, although inheritances may be more prevalent and on average worth more in *absolute* (£) terms for individuals higher up the wealth distribution, they are more important *relative to other wealth holdings* (i.e. as a % of wealth) for individuals lower down the wealth distribution.

The results of similar analysis for gifts are presented in Table 2.9. As with inheritances, individuals lower down the wealth distribution are less likely to be in households that have received substantial gifts than individuals higher up the wealth distribution, and any gifts that have been received make, on

**Table 2.9. Contribution of gift(s) to current net wealth**

	% in households that have received a gift	Mean contribution of gifts to household wealth per person (£, 2013)		Mean contribution of gifts to wealth across all individuals
		Across all individuals	Across recipients only	
All	9.9%	1,742	17,619	0.9%
Net wealth ≤£0	2.9%	248	8,483	–
<i>Those with positive net wealth</i>				
Least wealthy	5.1%	420	8,083	15.4%
Decile 2	6.9%	563	8,122	1.6%
Decile 3	9.0%	1,134	12,657	1.5%
Decile 4	9.1%	1,066	11,693	1.1%
Decile 5	9.4%	585	6,223	0.5%
Decile 6	9.7%	1,200	12,277	0.8%
Decile 7	12.9%	1,835	14,281	0.9%
Decile 8	11.3%	2,600	22,950	1.1%
Decile 9	12.9%	2,522	19,470	0.7%
Most wealthy	16.9%	6,473	38,256	0.7%

Note: Wealth deciles are defined on the basis of net household wealth per person for those with positive net wealth. The contribution of gifts to net wealth is calculated assuming they are capitalised at a real rate of 3% per year from the time of receipt. Unweighted N = 8,457.

<sup>17</sup> We set out Tables 2.8–2.10 in terms of deciles of total current wealth, rather than in terms of deciles of non-inherited wealth, since individuals' positions in the distribution of non-inherited wealth are sensitive to the assumptions made when calculating the contribution of transfers to current net wealth.

**Table 2.10. Contribution of total transfers to current net wealth**

	% in households that have received a transfer	Mean contribution of transfers to household wealth per person (£, 2013)		Mean contribution of transfers to wealth across all individuals
		Across all individuals	Across recipients only	
All	42.4%	23,255	54,602	11.5%
Net wealth ≤£0	16.8%	2,898	17,266	–
<i>Those with positive net wealth</i>				
Least wealthy	21.8%	3,387	15,296	124.0%
Decile 2	33.5%	8,140	24,201	23.3%
Decile 3	35.7%	7,927	22,141	10.8%
Decile 4	38.2%	10,232	26,781	10.3%
Decile 5	43.4%	12,644	29,118	10.0%
Decile 6	48.8%	23,811	48,361	15.1%
Decile 7	48.8%	22,399	45,688	11.6%
Decile 8	48.5%	26,598	54,459	10.8%
Decile 9	59.5%	47,222	78,813	14.0%
Most wealthy	62.3%	83,505	133,713	9.4%

Note: Wealth deciles are defined on the basis of net household wealth per person for those with positive net wealth. The contribution of transfers to net wealth is calculated assuming they are capitalised at a real rate of 3% per year from the time of receipt. Unweighted N = 8,457.

average, a lower absolute contribution to household wealth per person. However, the proportionate contribution of gifts to wealth is greater among those lower down the wealth distribution – particularly so among the 10% of individuals with the lowest (but still positive) net wealth – and so gifts are relatively more important for these individuals than for wealthier individuals.

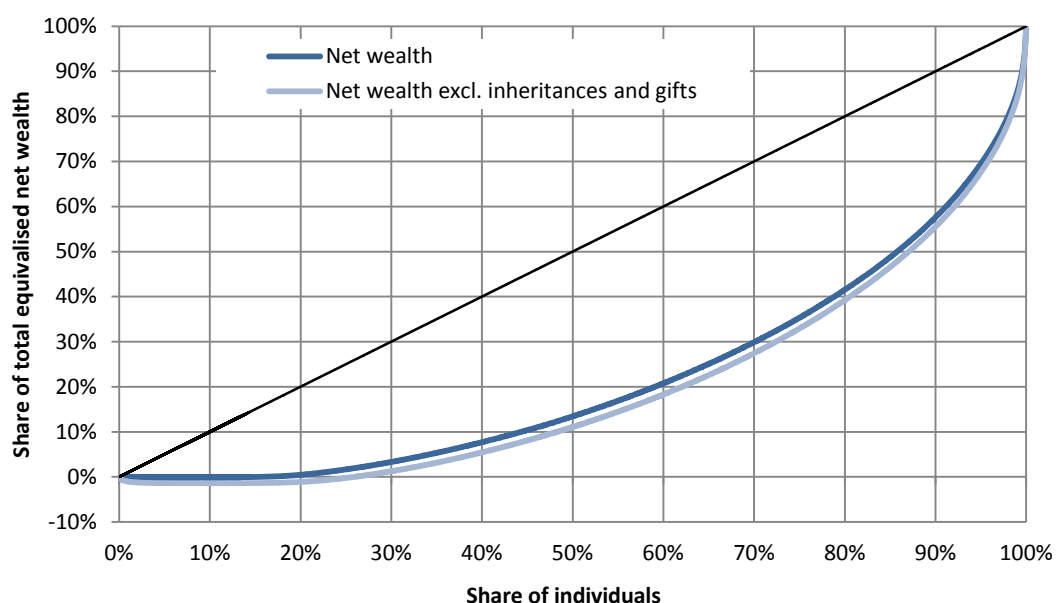

Combining the contribution of inheritances and gifts together (shown in Table 2.10), the same conclusions hold. Transfers are more prevalent and on average worth more in absolute terms for individuals higher up the wealth distribution, but they are more important relative to other wealth holdings for individuals lower down the wealth distribution.

#### **2.4.4 The impact of transfers on wealth inequality**

Inequality in the distribution of current net household wealth per person among ELSA respondents born in the 1920s to 1950s is illustrated by the Lorenz curve in Figure 2.9. The Gini coefficient for current household net wealth per person is 0.569. Wealth is therefore more equally distributed than either inheritances (the Gini for household inheritances per person is 0.871) or gifts (the Gini for substantial household gifts per person is 0.975).<sup>18</sup>

<sup>18</sup> These Gini coefficients are lower than the 0.903 reported for inheritances in Section 2.2.3 and the 0.987 reported for gifts in Section 2.3.3 since, if we assume inheritances and gifts are shared equally within couples, inequality in the value received by individuals would be lower than if we assumed individuals benefited only from their own inheritances or gifts.

**Figure 2.9. Contribution of inheritances and gifts to wealth inequality**

What has been the contribution of inheritances and reported gifts to this inequality in wealth? We can illustrate this by subtracting from each individual’s current net household wealth per person the estimated contribution of transfers as described above. The Lorenz curve for this resulting ‘net wealth excluding inheritances and gifts’ is also shown in Figure 2.9. The Lorenz curve for this measure of wealth actually lies slightly to the right of the Lorenz curve for current net wealth, indicating that if transfers were excluded, the distribution of wealth would be *less* equal; the Gini coefficient would be higher at 0.609. Inheritances and gifts have therefore had a small *equalising* impact on the distribution of wealth for these cohorts.<sup>19</sup>

This conclusion is perhaps surprising, given that inheritances and gifts are more likely to be received by, and are on average larger for, those with other indicators of social advantage (for example, higher education and higher income). The explanation is that described above: while transfers are more prevalent and on average worth more in absolute terms for individuals higher up the wealth distribution, they are more important *relative to other wealth holdings* for individuals lower down the wealth distribution, and therefore they have an equalising impact on the distribution of wealth.

The small equalising impact of transfers on the distribution of wealth is explored in more detail in Table 2.11, which illustrates how the shares of wealth held by different parts of the current net wealth distribution would differ were transfers excluded. The top 25% of the wealth distribution hold 64.7% of current net wealth, but if transfers were excluded from all individuals’ wealth holdings, they would hold 65.2% of wealth – in other

<sup>19</sup> Both inheritances and gifts individually have a small equalising impact on the distribution of wealth, though the impact of gifts is much smaller given their lower prevalence and typically smaller size. The Gini for net household wealth per person excluding just gifts would be 0.572 and the Gini for net household wealth per person excluding just inheritances would be 0.606.

words, wealth would be more concentrated among the wealthy. This is particularly the case for the top 1% of individuals, who would hold a 1.1 percentage point greater share of wealth excluding transfers than they do of current total wealth. At the other end of the wealth distribution, those in the bottom 25% hold a greater share of current net wealth (1.7%) than they would if transfers were excluded (1.2%). Inheritances and gifts are therefore estimated to have reduced wealth inequality by increasing the share of wealth held by the bottom 25% and reducing the share of wealth held by the top 25% (more specifically, the share of wealth held by the top 1%).

One potential concern with the finding that transfers have a small equalising impact on the distribution of wealth might be that it arises by construction from life-cycle effects. For example, if households decumulate their wealth as

**Table 2.11. Shares of wealth held by parts of the current net wealth distribution**

Share of wealth held by:	Total net wealth	Total net wealth excluding transfers	<i>Difference due to transfers</i>
<b>Top 25%</b>	<b>64.7%</b>	<b>65.2%</b>	<b>-0.5%</b>

Next 5%	0.0%	0.0%	0.0%
Next 4%	0.0%	0.0%	0.0%
Bottom 1%	-0.1%	-0.2%	0.2%

Note: Individuals are sorted according to their current total net household wealth per person.

**Table 2.12. Inequality in net wealth including and excluding transfers**

	All	Cohort			
		1920s	1930s	1940s	1950s
<b>Gini coefficient for:</b>					
Net household wealth per person	0.569	0.535	0.540	0.556	0.599
Net hh wealth pp excl. inheritances	0.606	0.575	0.584	0.595	0.630
Net hh wealth pp excl. gifts	0.572	0.541	0.541	0.559	0.600
Net hh wealth pp excl. inheritances <i>and</i> gifts	0.609	0.581	0.586	0.600	0.632
<i>Increase in Gini from excluding inheritances</i>	<i>0.037</i>	<i>0.040</i>	<i>0.044</i>	<i>0.039</i>	<i>0.031</i>
<i>Increase in Gini from excluding gifts</i>	<i>0.002</i>	<i>0.005</i>	<i>0.001</i>	<i>0.003</i>	<i>0.002</i>
<i>Increase in Gini from excluding transfers</i>	<i>0.040</i>	<i>0.046</i>	<i>0.046</i>	<i>0.044</i>	<i>0.034</i>

they age, then older households will have lower current wealth, and therefore be calculated as having a higher proportionate contribution from a given transfer, than otherwise equivalent younger households. It could then be this that drives the greater proportionate contribution of transfers to wealth among the less wealthy, rather than transfers being relatively more important for the less wealthy among individuals at the same stage of the life cycle. Table 2.12, however, illustrates that the exclusion of transfers affects the distribution of net household wealth per person in a similar way for each cohort in our sample. This suggests that the result is not simply being driven by life-cycle effects or by other cohort differences in wealth holdings and/or transfers.<sup>20</sup>

***Sensitivity analysis***

As described in Section 2.4.2, to estimate the contribution of transfers to current net wealth (and therefore the impact of transfers on the distribution of wealth), we need to make two important assumptions: how much of transfers has been saved and what interest rate the saved proportion of transfers will have been capitalised at since the time they were received. In this subsection, we illustrate how sensitive our main results are to these assumptions.

In the above analysis, we have assumed that individuals have accrued a 3% a year real rate of return on their inheritances and gifts. Table 2.13 illustrates how our main results would differ were we to make alternative assumptions about the interest rate. Assuming a lower rate of return (2% per year) results in

**Table 2.13. Sensitivity of main results to interest rate assumption**

	Assumed real interest rate			
	Baseline (3%)	2%	4%	Varies with wealth <sup>a</sup>
Mean contribution of transfers to wealth (%)	11.5	10.0	13.4	13.8
Gini of net wealth	0.569	0.569	0.569	0.569
Gini of net wealth excl. transfers	0.609	0.600	0.625	0.619
<i>Change in Gini from transfers</i>	<i>-0.040</i>	<i>-0.030</i>	<i>-0.055</i>	<i>-0.050</i>
<i>Change, due to transfers, in share of wealth held by:</i>				
Top 1%	-1.1%	-1.0%	-1.3%	-1.2%
Top 25%	-0.5%	-0.5%	-0.6%	0.5%
Next 25%	0.2%	0.2%	0.2%	-0.1%
Next 25%	-0.2%	-0.1%	-0.2%	-0.6%
Bottom 25%	0.5%	0.4%	0.6%	0.3%

<sup>a</sup> Real interest rate is assumed to be 0% for those with negative or zero current net wealth, 1% for those in the lowest two deciles of the current net wealth distribution (conditional on positive net wealth), 2% for those in the next two deciles, 3% for those in the middle two deciles, 4% for those in the next two deciles and 5% for those in the top two deciles of the current net wealth distribution.

<sup>20</sup> This is also consistent with the findings of Crawford and Tetlow (2012), who illustrated relatively little decumulation of non-pension wealth during retirement.

a lower estimated contribution of transfers to current net wealth (10.0% rather than 11.5%) and a smaller (but still equalising) impact of transfers on the distribution of wealth as measured by the Gini coefficient. Conversely, if we were to assume a higher rate of return (4% per year), transfers would be estimated to have contributed 13.4% of current net wealth and to have had a greater (albeit still small) equalising impact on the distribution of wealth.

One could argue, however, that not all individuals benefit from the same interest rate. In particular, it is possible that wealthier individuals are able to benefit from higher interest rates, either because they are more experienced or knowledgeable about how to get a better return or because greater wealth gives access to financial instruments with greater returns that would not otherwise be available. Assuming an interest rate that is increasing in wealth could have important implications for our finding that inheritances are wealth equalising, since it could increase our estimate of the contribution of transfers to wealth among wealthier individuals and reduce it among less wealthy households. However, the final column in Table 2.13 illustrates that when we assume an interest rate that varies from 0% to 5% depending on current net wealth, inheritances and gifts are still wealth equalising in that they reduce the Gini coefficient for the wealth distribution. In other words, even with this varying interest rate, transfers are still estimated to be relatively more important for those in the lowest wealth quintiles than for those with higher levels of wealth.<sup>21</sup>

In all the sensitivity tests described in Table 2.13, we have varied the interest rate at which inheritances and substantial gifts are assumed to have been capitalised. However, as discussed in Section 2.4.2, transfers could also affect the interest rate that an individual is able to get on their other wealth as well (for example, if an inheritance is combined with other wealth to provide a deposit on a house). This is potentially very important, since such an effect could increase the relative importance of transfers for those who had larger amounts of non-inherited wealth and reduce or undo the wealth-equalising impact of transfers that we describe above. Unfortunately, we are not able to test the sensitivity of our results to this, since we do not know what other wealth each household had at the time an individual received their gift or inheritance, and so this must simply be kept in mind as a potential caveat to our results.

In the results described above, we have assumed that all transfers are completely saved. As discussed in Section 2.4.2, if instead all transfers were completely consumed (i.e. the transfer is spent on something the individual would not have purchased in the absence of the transfer), then transfers would have no effect on current wealth or on wealth inequality (though they would, of course, affect consumption inequality and lifetime utility). Table 2.14 illustrates the sensitivity of our main results to alternative intermediate assumptions about the proportion of any inheritance or gift that is saved (as opposed to consumed). Assuming a 75% saving rate for all individuals

---

<sup>21</sup> Table 2A.5 in the appendix provides the mean estimated contribution of transfers to wealth for each decile of the wealth distribution under the alternative interest rate assumptions.

**Table 2.14. Sensitivity of main results to assumption on proportion saved**

	Share of transfer saved			
	Baseline (100%)	75%	50%	Varies with wealth <sup>a</sup>
Mean contribution of transfers to wealth (%)	11.5	8.6	5.7	9.3
Gini of net wealth	0.569	0.569	0.569	0.569
Gini of net wealth excl. transfers	0.609	0.593	0.580	0.584
<i>Change in Gini from transfers</i>	<i>-0.040</i>	<i>-0.023</i>	<i>-0.011</i>	<i>-0.015</i>
<i>Change, due to transfers, in share of wealth held by:</i>				
Top 1%	<i>-1.1%</i>	<i>-0.8%</i>	<i>-0.5%</i>	<i>-0.8%</i>
Top 25%	<i>-0.5%</i>	<i>-0.4%</i>	<i>-0.3%</i>	<i>0.8%</i>
Next 25%	<i>0.2%</i>	<i>0.1%</i>	<i>0.1%</i>	<i>-0.2%</i>
Next 25%	<i>-0.2%</i>	<i>-0.1%</i>	<i>-0.1%</i>	<i>-0.6%</i>
Bottom 25%	<i>0.5%</i>	<i>0.4%</i>	<i>0.2%</i>	<i>-0.1%</i>

<sup>a</sup> The share of transfers assumed to be saved is 0% for those with negative or zero current net wealth, 20% for those in the lowest two deciles of the current net wealth distribution (conditional on positive net wealth), 40% for those in the next two deciles, 60% for those in the middle two deciles, 80% for those in the next two deciles and 100% for those in the top two deciles.

roughly halves the impact of transfers on wealth inequality, while assuming a 50% saving rate for all individuals roughly halves the impact of transfers on wealth.

As with interest rates, it is possible to argue that the savings rate itself varies with wealth – in particular, there is evidence that suggests that those with higher lifetime incomes have higher savings rates (see, for example, Dynan et al. (2004)). The final column of Table 2.14 therefore explores the implications of assuming a savings rate that varies with wealth, from 0% among those with negative or zero current net wealth, to 100% among those in the highest two deciles of the current net wealth distribution. This has the effect of reducing the contribution of inheritances to wealth more among those with the lowest current net wealth than among those with the highest levels of current net wealth (see Table 2A.6 in the appendix). However, even so, we still estimate that inheritances and gifts are relatively more important among those with the lowest levels of net wealth, and therefore we still find transfers overall to be wealth equalising, although the effect is much smaller than under our baseline assumptions, and the impact on different parts of the wealth distribution is less clear-cut.

## 2.5 Conclusions

The inclusion in ELSA wave 6 of questions on the lifetime receipt of inheritances and gifts has made an important improvement in the data available to researchers. For the first time, we have data on the lifetime receipt of inheritances and gifts, alongside detailed wealth statistics, for a large representative sample of today's older individuals. In this chapter, we have

used these new data to document the pattern of inheritances and large gifts received by those born in the 1920s to 1950s (inclusive) and illustrated the impact of these transfers on the distribution of wealth.

Over a quarter (28.2%) of individuals born between 1920 and 1959 report having received an inheritance and 7.0% report having received a substantial gift. This is a lower prevalence of transfers than was reported in the Attitudes to Inheritance Survey, over which there might be some concern about its representativeness. However, the pattern of recipients is found to be similar. In particular, women are more likely to have received an inheritance than men, those with higher levels of education are more likely to have received an inheritance than those with lower levels of education, those with higher levels of income are more likely to have received an inheritance than those with lower levels of income, and those of white ethnicity are more likely to have received an inheritance than those of non-white ethnicity. Among those who have received an inheritance, those with higher levels of education on average received larger amounts than those with lower levels of education, and those with higher levels of income on average receive larger amounts than those with lower levels of income.

A particular advantage of the ELSA data is that we can distinguish between life-cycle timing effects and cohort differences. Such analysis clearly demonstrates an increasing prevalence of inheritances among later cohorts – as might be expected given increasing homeownership rates and increasing wealth among these cohorts' parents' generations. There is also some evidence of increasing prevalence of gifts, although we are more tentative over this conclusion due to concerns that smaller gifts may not be consistently captured across different cohorts.

We estimate that, assuming inheritances and gifts have been saved since they were received and accrued a 3% a year real return, taken together these transfers would be responsible for 11.5% of current net household wealth holdings among individuals born in the 1920s to 1950s. Transfers are found to be more prevalent, and on average worth more in absolute terms, for individuals higher up the current net wealth distribution. However, they are more important relative to other wealth holdings for individuals lower down the wealth distribution, and therefore they have a small equalising impact on the distribution of wealth. This confirms the findings of Karagiannaki and Hills (2013); however, these authors were cautious about drawing this conclusion because of the more limited nature of the data underlying their analysis.

The finding that transfers have a small equalising direct impact on the distribution of wealth is robust to alternative assumptions over the interest rate received on transfers and over the proportion of transfers saved, when the same assumptions are applied to all individuals. When the interest rate received or the proportion of transfers saved is assumed to vary with wealth, the effects are more complex, but the scenarios considered in this chapter still suggest that transfers, if anything, have a small equalising impact. We are unable to test, however, the sensitivity of our results to the argument that transfers enable a greater interest rate on other non-inherited wealth, and so this remains a potential caveat to our results.

Having established these patterns of intergenerational transfers for today's older individuals, the important question for future research will be how these trends might differ for later cohorts. On the one hand, individuals in later cohorts might feel a greater 'need' for transfers from their parents to meet expenditure needs that their parents did not face – such as university costs and large housing deposits – or simply to finance their retirements (in particular given the declining availability of typically more generous defined benefit pensions in the private sector). On the other hand, their parents and others in older generations may not have such capacity to provide *inter-vivos* gifts or bequests, given their increasing retirement lengths and rising cost pressures in older age such as for social care needs. Investigating empirically how these competing influences might affect trends in intergenerational transfers in future is therefore an important avenue for future research.

Most wealthy	9.4%	7.0%	4.7%	9.4%

<sup>a</sup> The share of transfers assumed to be saved is 0% for those with negative or zero current net wealth, 20% for those in the lowest two deciles of the current net wealth distribution (conditional on positive net wealth), 40% for those in the next two deciles, 60% for those in the middle two deciles, 80% for those in the next two deciles and 100% for those in the top two deciles.

# 3. The evolution of lifestyles in older age in England

**Katey Matthews** *University of Manchester*

**Panayotes Demakakos** *University College London*

**James Nazroo** *University of Manchester*

**Aparna Shankar** *University College London*

Cross-sectional data can be used to describe differences in lifestyles across different age groups, or cohorts. However, this does not tell us how lifestyles change as individuals grow older and which events and characteristics are associated with age-related lifestyle changes. In this chapter, we are concerned with showing how and why lifestyles change as people grow older. To be more precise, the focus is on the evolution of forms of social engagement and behaviour. Lifestyle choices, such as health behaviours and engagement in societal and cultural activities, are in part set in early life, reflecting how preferences are shaped by socio-economic and age cohort contexts, but they are also shaped by external influences in later life, such as declining physical health, retirement, widowhood and other personal changes. The multidisciplinary nature of ELSA and its cross-cohort longitudinal design make it uniquely placed to examine several different dimensions of lifestyle, how they relate to each other, how they change in relation to age and life stage, and how these changes might vary across cohorts.

The dimensions of lifestyle covered by this chapter include social and civic engagement (i.e. volunteering, group membership and number of social contacts), cultural engagement (i.e. visiting the cinema, restaurants, museums and theatres), consumption (i.e. spending on holidays, takeaways and restaurants, clothes and household goods) and health behaviours (i.e. smoking, frequency of drinking and occupational and leisure-time physical activity). First, trajectories of changes in lifestyle behaviours are mapped by age, gender, education and wealth. Second, changes in these lifestyle factors are identified in response to events such as retirement, widowhood, onset of disease and onset of physical or cognitive impairment.

The cross-sectional analysis in this chapter shows that:

- In 2012–13, people aged 50 and over were consistently more likely to engage in lower, rather than higher, levels of social or civic engagement, yet more likely to engage in higher levels of cultural engagement than lower. The proportion of heavy drinkers and smokers was low.
- Around 30 to 40% of all older adults in 2012–13 had sedentary lifestyles or took part in only low-level physical activity. Women were slightly less likely than men to have lifestyles characterised by moderate or high physical activity.

## *Evolution of lifestyles*

- Older age groups were less likely to show high or medium social and civic or cultural engagement, higher levels of consumption and higher levels of physical activity than younger age groups, especially from age 70 onwards.
- There was a strong relationship between wealth and all types of lifestyle behaviour in 2012–13. Older adults with higher levels of wealth were more likely to engage in high or medium social and civic or cultural activities, have higher rates of consumption and have higher physical activity levels than those who are poorer. Higher wealth was associated with a reduced likelihood of smoking but an increased likelihood of drinking daily. In each instance, a gradient pattern over wealth groups was observed. Levels of education showed the same pattern.
- Individuals' self-rated health status was an important predictor of lifestyle behaviour. Poorer health was associated with lower levels of social and civic engagement, cultural engagement, consumption and physical activity. Those in poorer health were also significantly more likely to be smokers but less likely to drink daily.
- Those who had no access to a car when needed were significantly more likely to show low levels of social and civic and cultural engagement, lower consumption and lower levels of physical activity. Lack of car access was also associated with an increased likelihood of being a smoker. Having no access to public transport was associated with low levels of social and civic and cultural engagement and physical activity.

The longitudinal analysis in this chapter shows that:

- The majority of older adults did not change their lifestyle behaviours over the period 2002–03 to 2012–13.
- Wealth, education and health are key drivers of changes in levels of social and civic engagement. People with higher wealth and education and better health are less likely to ever display low levels of engagement.
- Wealth is the largest driver of changes in cultural engagement. Those with higher wealth are more likely to remain in stable high engagement or to move between high and medium levels of engagement. Higher wealth is consistently associated with a reduced likelihood of ever displaying low levels of cultural engagement.
- Stopping smoking is more likely among those with higher levels of wealth than lower, and both reducing and increasing alcohol intake are more common among those with poorer self-rated health. Levels of physical activity reduce with age, and higher levels of physical activity are strongly associated with higher wealth and better self-rated health.
- Becoming retired is associated with moving into lower levels of consumption, as well as with continued low consumption. Those who became retired also moved from both high and medium physical activity levels to low.
- Becoming widowed is associated with increases in both social and civic engagement and cultural engagement.

- The onset of frailty is associated with a decrease in both social and civic and cultural engagement, stopping smoking and a reduction in levels of physical activity.
- Losing access to a car is associated with reduced social and civic engagement and a decrease in levels of physical activity.

### **3.1 Introduction**

Previous research has indicated that engagement in healthy and active lifestyle behaviours in later life is associated with positive outcomes. Studies have found that higher involvement in social and cultural activities and a greater number of social contacts are associated with lower levels of depression, higher subjective well-being, improved physical and cognitive function and lower mortality risk (de Leon et al., 2003; Glass et al., 2006; Niti et al., 2008; Chiao et al., 2011; Thomas, 2011). Better health behaviours, such as not smoking, keeping within recommended alcohol limits and increased physical exercise, have also been associated with better physical and mental health across the life course, and there is evidence to suggest maintenance of these behaviours is equally important in older age (LaCroix et al., 1991; Blow et al., 2000; Brach et al., 2004; Gow et al., 2012).

Societal engagement in later life may provide a useful means of benefiting well-being through various mechanisms. Participating in enjoyable social roles around the time of workforce exit might make for easier transitions into retirement by compensating for the loss of work roles (Adams, Leibbrandt and Moon, 2011) and, where activities are rewarding, such as voluntary work, a continued sense of social identity can be maintained (Drentea, 2002). Such ideas tie in with continuity and activity theories, which promote participation in socially rewarding roles over the retirement process in order to increase mental well-being and life satisfaction. Increased social integration gained by participation in societal activities may lead to increased knowledge on healthy lifestyle behaviours and healthcare resources (Thomas, 2011). It is important to note, however, that causal mechanisms are not clear, and it is uncertain whether reverse causality of an effect of health on engagement is more important than the potential effects of engagement on health. Social networks might also provide a useful means of dealing with death of a spouse in later life (Isherwood et al., 2012), and participation in social activities has also been associated with a better ability to deal with the impact of stressful life events, such as the loss of a spouse or onset of disease (Utz et al., 2002).

If there is evidence of health effects of various lifestyle behaviours in later life, it is important to understand the drivers of both initial behaviours and subsequent changes in behaviours. Where there are barriers to activity – for example, through disability, lack of access (for example, by means of public transport) or unaffordability – policymakers are keen to communicate with local communities, businesses and voluntary groups in order to better facilitate social and active lives for older people. Between March and December 2011, the government funded the ‘Active at 60’ programme, which helped older people become more physically active and engage with society through cultural and social activities. The project was aimed at those identified as

being at higher risk of social isolation due to low income or disability (Hatamian et al., 2012). Research that continues to distinguish groups at risk of lower cultural and social engagement and poor health behaviours in later life may encourage policymakers to establish similar programmes.

This chapter is structured as follows. Section 3.2 outlines the methods used for the analysis, including the construction of our dimensions of lifestyle. Section 3.3 outlines the different types of lifestyle behaviours by dimension identified through means of latent class analysis and Section 3.4 describes changes in trends of these behaviours between 2002–03 and 2012–13 for older men and women individually. Section 3.5 examines the socio-demographic and socio-economic factors associated with different lifestyle behaviours. An overview of individual change in lifestyle behaviours is presented in Section 3.6, and Section 3.7 demonstrates how trajectories of lifestyle behaviours are affected by external influences such as the onset of retirement, the death of a spouse, the onset of frailty and loss of access to private and public transport. Section 3.8 concludes.

## **3.2 Methods**

### **3.2.1 Sample**

The analysis uses core members from wave 1 of ELSA who responded to at least two consecutive waves of the data from wave 1 onwards. This includes people who were aged 50 and over in 2002–03. Weights are used in all analyses to account for non-response.

### **3.2.2 Measures of lifestyle behaviours**

We constructed four key domains of lifestyle based on the assessment of selected types of behaviour over time. These are social and civic engagement, cultural engagement, consumption, and health behaviours. These four dimensions were chosen as they represent four different aspects of behaviour in older life, and each is likely to be affected by changes in personal circumstances, such as the death of a partner, exit from the workforce or the onset of illness or frailty. The items comprising each of the domains are listed below.

#### ***Social and civic engagement***

The level of social and civic engagement is assessed through questions on membership of a political party; a church or religious group; a charitable association; a community-based organisation (such as a neighbourhood watch group); an educational group or class; a social club; a sports club, gym or exercise class; another social-based organisation or society; number of social contacts (children, other relatives or friends with whom the respondent meets up with once a week or more often); and whether or not the individual had participated in voluntary work in the last month.

#### ***Cultural engagement***

The level of cultural engagement is assessed through questions on visiting a cinema, restaurant, art gallery or museum, or a theatre at least once in the last year.

### ***Consumption***

Consumption is first measured in terms of the total amount spent on durables, including white goods, electrical goods and digital or cable television, in the last four weeks, the amount spent on eating out and takeaways in the last four weeks and the amount spent on clothes in the last four weeks. Second, consumption is assessed through questions on whether or not the individual has been on holiday in the UK or abroad in the last year.

### ***Health behaviours***

Health behaviours are defined in terms of smoking (current smoker vs. non-smoker), frequency of alcohol consumption (daily or almost daily vs. other) and levels of physical activity. Physical activity is measured as the amount of moderate or vigorous activity participated in more than once a week, or participation in occupations that involve physical work or manual labour. The variable is split to show those who participate in high, medium and low physical activity (the low category also includes people with sedentary lifestyles).

### **3.2.3 Classificatory measures**

The analysis uses age, sex and marital status as socio-demographic measures. Wealth, education and employment status (including retired) were used as a measure of socio-economic position. Self-rated health and a binary measure of frailty were used to account for individual health. Models also include a measure of transport accessibility. Predictor variables used are onset of widowhood, retirement and frailty, and loss of car access or access to public transport.

#### ***Socio-demographic***

- Age is grouped into four categories: 50–59, 60–69, 70–79 and 80 and over. The analysis uses a baseline measure of age to control for potential age effects on changes in lifestyle behaviour.
- Marital status is a four-category variable comprised of those who are single (i.e. never married or in a civil partnership and not cohabiting); married / in a civil partnership or cohabiting; separated or divorced and single; and widowed and single.

#### ***Socio-economic***

- Wealth is measured as total household non-pension wealth. This includes all financial assets, property, other physical assets and any businesses owned by the individual and their partner (where applicable). The measure is net of debt, including mortgages. Individuals are grouped by the family unit into quintiles 1 to 5 from lowest wealth to highest wealth.
- Education is measured using the age an individual first left full-time education. Individuals are grouped into three categories: those who left at or before the compulsory school-leaving age that applied in the UK to their cohort (referred to as ‘low’ education); those leaving school after compulsory school-leaving age but before age 19 (referred to as ‘mid’

## *Evolution of lifestyles*

education); and those leaving at or after age 19 (referred to as 'high' education).

- Employment status is a four-category variable according to the respondent's employment status at the time of interview. The categories are retired, full-time employment, part-time employment and 'other', which comprises those who are unemployed, permanently sick or disabled, or looking after family members.

### *Health*

- Self-rated health is a five-category variable with response categories as follows: excellent, very good, good, fair and poor.
- Frailty is measured using the Rockwood Frailty Index, which is comprised of items concerning mobility and difficulties with activities of daily living; indicators of cardiovascular disease and chronic disease; visual and hearing capability; symptoms of depression; cognitive function; and whether or not the individual has suffered pain while walking, hip fractures and joint replacement. The index has a potential score range of 0 to 1, where a higher value represents a greater number of indications of frailty. This analysis uses index scores of 0.2 and above to signify frailty.

### *Access to a car*

- A person has access to a car if they state they have access to a car or van when needed, as either a driver or a passenger.

### *Access to public transport*

- A person has access to transport if they have access to a car when needed (as a driver or passenger) or use public transport. Lack of access to transport is denoted by no car access when needed and infrequent use of public transport (once a month or less) combined with an access restriction such as unaffordability, unreliability or a health condition that prevents them from using it.

### *Predictor variables*

- *Retirement:* As part of the aforementioned employment status variable, an individual is classed as retired if they state they are retired and do not simultaneously state any other economic situation, such as part-time work or absence from the workforce due to unemployment, redundancy or disability. A person is classed as becoming retired if they are retired at the wave of interest but were in either full- or part-time employment at the wave before.
- *Being widowed:* An individual is classed as widowed if they have stated themselves as widowed and single when asked to describe their marital status. A person is classed as becoming widowed if they state themselves to be widowed and single at the wave of interest but are married or in a civil partnership at the wave before.

- *Becoming frail*: An individual is classed as becoming frail if they have an index score of 0.2 or above but have a score below 0.2 at the previous wave.
- *Losing access to transport*: An individual is classed as losing access to transport if they have access to either a car or public transport at the previous wave but have neither at the following wave.

### **3.2.4 Analysis**

There are two sets of analyses presented in this chapter. Initially, latent class analysis was used to identify latent classes of behaviours for three of the four lifestyle dimensions.<sup>1</sup> Basic cross-sectional analysis of class membership, including frequencies and proportions of class members, was then carried out for each wave in order to identify whether there has been population change in lifestyle behaviours according to socio-demographic and socio-economic circumstances during 2002–03 to 2012–13. Logistic regression models are used to predict class membership according to individual socio-demographic and socio-economic characteristics, as well as by measures of health and access to transport.

The second part of the analysis observes movement between classes over time for core sample members aged 50 and over in wave 1 who have responded to at least two consecutive waves of ELSA. The analysis examines potential age-related drivers of movement between types of lifestyle behaviour, i.e. becoming retired, becoming widowed, becoming frail, and losing access to private or public transport. Logistic regression models are used to assess the impact of these changes in circumstances on lifestyle behaviours whilst controlling for socio-demographic and socio-economic characteristics.

## **3.3 Latent classes of lifestyle behaviours: cross-sectional analyses between 2002–03 and 2012–13**

Latent class analysis identified three classes of lifestyle behaviour for social and civic engagement, cultural engagement and consumption behaviour. The classes are outlined below and full tables of class information are provided in the appendix to this chapter (Tables 3A.1–3A.3).

### **3.3.1 Social and civic engagement**

A high, medium and low social and civic engagement class was identified for each wave of the data, each of which was similar enough to be compared longitudinally. In the high engagement class, the majority of people belonged to three or four social or civic organisations or groups, although the proportion became slightly lower from wave 3 onwards as the sample aged. In the medium engagement class, the majority of people were engaged in one or two

---

<sup>1</sup> Latent class analysis did not identify meaningful classes on the basis of the health behaviour items. Health behaviour items will subsequently be examined individually.

organisations or groups, and in the lowest engagement class the majority were engaged in one or none. The majority of people in the high engagement class had one or two family members or friends they had contact with weekly, whilst in the medium class the majority of people had between zero and two contacts and in the low class most people had one or two close contacts. Between 80 and 90% of the high engagement class had taken part in voluntary work over the last month (with the exception of wave 1, where the proportion was just over 50%); this proportion was between 59 and 74% for the medium class and 7% or less for the low class.

### **3.3.2 Cultural engagement**

A high, medium and low cultural engagement class was identified for each wave of the data and again these were similar enough across waves to be examined longitudinally. In the high engagement class, between 86 and 90% of people visited the cinema, close to 100% of people ate at restaurants, 89 to 92% of people visited art galleries and museums and 97 to 98% of people went to the theatre. In the medium class, 20 to 34% of people visited the cinema, 95 to 98% of people ate at restaurants, 19 to 46% of people visited art galleries and museums and between 21 and 52% of people went to the theatre. In the low engagement class, 6% or less of people visited cinemas, art galleries and museums or the theatre, and between 50 and 66% of people ate out at restaurants.

### **3.3.3 Consumption**

Three classes of consumption behaviour were identified.<sup>2</sup> Two smaller higher-consumption classes were distinguishable from one another by different distributions in spending. The first class showed an even distribution of spending among different categories of goods, with the most spent on durables, the second most spent on food and the least spent on clothes. Between 72 and 83% of this class had taken a holiday in the UK within the last year and between 72 and 88% had taken a holiday abroad. The second class spent considerably more money on durables and clothes but considerably less money on food. Between 70 and 79% of people in this class had taken a holiday within the UK in the last year, and between 55 and 75% had taken a holiday abroad. The third class identified was the largest and spent well below the first two groups on durables, food and clothes, although spending among this group was average for the ELSA sample as a whole. Within this class, between 55 and 57% of people had taken a holiday in the UK in the last year and between 41 and 47% had taken a holiday abroad.

### **3.3.4 Health behaviour**

Latent class analysis could not be used to construct classes of health behaviour, because there is very little variation in rates of smoking and heavy drinking in the ELSA data, and the three distinct categories of physical activity level (high, medium and low or sedentary) are not latent classes on their own. Consequently, this analysis will examine predictors of changes in health

---

<sup>2</sup> The variables used to construct classes of consumption behaviour were only recorded from wave 2 onwards. Subsequently, consumption is measured across the period 2004–05 to 2012–13, rather than 2002–03 to 2012–13.

behaviours on the basis of these three items of health behaviour separately. Descriptive statistics of these behaviours are discussed in the following section.

### **3.4 Population change in lifestyle behaviours: longitudinal analyses between 2002–03 and 2012–13**

The prevalence of class membership and specific health behaviours during 2002–03 to 2012–13 is shown for each dimension of lifestyle behaviour by sex in Figure 3.1. The proportion of older adults within each class remained fairly stable at each wave of data between 2002–03 and 2012–13.

Across all waves, older adults were more likely to belong to the class of low social and civic engagement, although there is a slight general decline in membership of this class over time, from 70% of all cases at wave 1 to 64% at wave 6. The classes of high and medium engagement see a small increase in the number of members over time. Across all waves, a slightly higher number of men than women belong to the low engagement class. (Figure 3.1a)

Across all waves, older adults are least likely to belong to the class representing low cultural engagement and, with the exception of wave 1, the majority belong to the class representing high cultural engagement. There is a slight general increase in the number of cases in the high engagement class over time, with 60% of all cases belonging to the high engagement class at wave 2 and 66% at wave 6. (Figure 3.1b)

The latent class analysis of consumption identified three slightly different groups of people on the basis of their spending behaviour. A class of ‘low’ consumption is actually comprised of those who spend amounts on all products which are close to the average spending of the ELSA sample overall. There are then two classes of higher consumption. The first of these comprises individuals who spend more than average and who show an even distribution of spending across food, clothes and durables (high consumption). The second of the higher consumption classes represents those who spend disproportionately higher amounts on durables and clothes than on food (medium consumption). Class membership remains stable during 2004–05 to 2012–13. Across all waves, older adults are more likely to belong to the class representing lower (average) consumption of all items. With the exception of wave 4, when there is a noticeable drop in cases, there is a slight increase in the percentage of cases belonging to the higher consumption class, from 4% at wave 2 to 7% at wave 6. Men are consistently slightly more likely to belong to the higher consumption group than women. (Figure 3.1c)

Health behaviours remained reasonably stable across each data period. Individuals are predominantly non-smokers and drink less often than daily or almost daily. There is a small but steady decrease in the proportion of smokers and heavy drinkers over time. Men are more likely to be heavy drinkers than women at any time point. (Figure 3.1d)

**Figure 3.1. Prevalence of class membership in each domain, by sex, 2002–03 to 2012–13**

**a) Social and civic engagement**

**b) Cultural engagement**

**c) Consumption**

**d) Health behaviours**

**Smoking**

**Alcohol consumption**

**Physical activity**

Only a minority of individuals take part in high levels of physical activity, and this proportion decreases as the sample ages. Women are slightly less likely to take part in high levels of physical activity than men and slightly more likely to be sedentary or involved in low-level physical activity. There is a small increase in sedentary behaviour / low activity between 2002–03 and 2012–13, which is to be expected as the population ages. (Figure 3.1d)

### 3.5 Lifestyle behaviours in 2012–13: examining lifestyles with classificatory measures

Table 3A.4 presents odds ratios predicting membership of the different lifestyle behaviour groups for each dimension of behaviour by socio-demographic and socio-economic variables, health, frailty, access to a car and access to public transport. Significant odds ratios are highlighted in bold. Multinomial logistic regression models were used to estimate odds ratios for membership of each group. Figures 3.2–3.11 show the significant odds ratios for each of the classificatory measures.

#### 3.5.1 Age group

**Figure 3.2. Significant odds ratios of behaviour type, by age group (ref: 50–59 years)**

Note: Only significant odds ratios are reported. See Table 3A.4 for the full model estimates.

Older age is consistently associated with reduced engagement, consumption and physical activity. In each instance, those aged 80 and over are the least likely to be in high or medium social and civic or cultural engagement. They are also the least likely to belong to the high or medium consumption groups or to participate in high or medium physical activity. These associations between lifestyle and age persist even after the other factors included in the model have been accounted for.

### 3.5.2 Sex

**Figure 3.3. Significant odds ratios of behaviour type, by being female (ref: male)**

Note: Only significant odds ratios are reported. See Table 3A.4 for the full model estimates.

Females are consistently more likely to belong to high or medium social and civic or cultural engagement groups than men. However, they are less likely than men to participate in high- or medium-level physical activity. They are less likely than men to either smoke or drink alcohol on a daily or almost daily basis.

### 3.5.3 Marital status

**Figure 3.4. Significant odds ratios of behaviour type, by marital status (ref: married, in a civil partnership or cohabiting)**

Note: Only significant odds ratios are reported. See Table 3A.4 for the full model estimates.

Being married, in a civil partnership or cohabiting is associated with higher social and civic engagement yet lower cultural engagement. Those who are single, widowed, or divorced or separated are almost twice as likely to belong to the high or medium cultural engagement classes as those who are married, in a civil partnership or cohabiting. Those who are single are over twice as likely to belong to the high or medium consumption groups than those who are in a couple. Being single, divorced or separated, or widowed is also associated with a higher likelihood of participating in high- or medium-level physical activity. Those who are widowed are more likely to smoke than those who belong to a couple, but there are no associations between marital status and daily drinking.

### 3.5.4 Wealth

**Figure 3.5. Significant odds ratios of behaviour type, by wealth quintile (ref: poorest)**

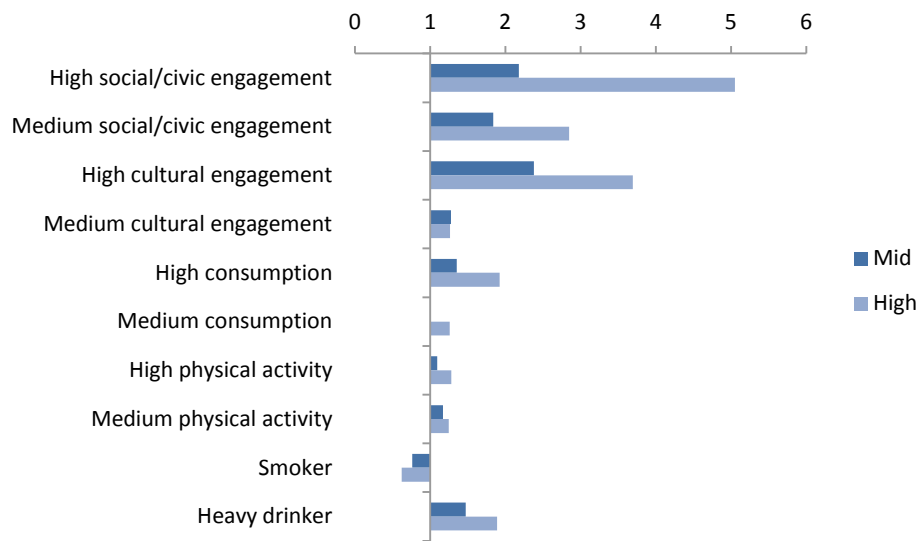

Note: Only significant odds ratios are reported. See Table 3A.4 for the full model estimates.

Wealth is strongly associated with all dimensions of lifestyle behaviour. Those in the richest wealth quintile are over four times as likely to belong to the high social and civic engagement group as those in the poorest, and over six times as likely to belong to the high cultural engagement group. They are also seven times more likely to belong to the highest consumption group. Higher wealth is also associated with higher physical activity, heavy drinking and lower chances of being a smoker. The relationship between wealth quintile and behaviour shows a strong gradient pattern, with higher engagement and better health behaviour consistently observed more with each increasing quintile.

### 3.5.5 Education

**Figure 3.6. Significant odds ratios of behaviour type, by education (ref: low)**

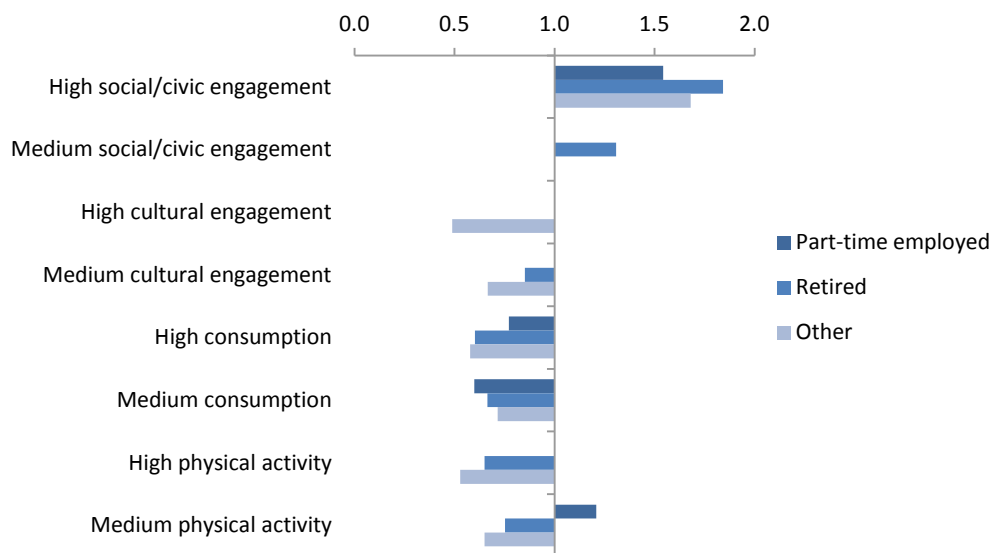

Note: Only significant odds ratios are reported. See Table 3A.4 for the full model estimates.

Education follows a similar pattern to wealth. The highest levels of education are consistently associated with the highest levels of engagement, consumption and physical activity. Those who are more highly educated are less likely to smoke.

### 3.5.6 Employment status

**Figure 3.7. Significant odds ratios of behaviour type, by employment status (ref: full-time employed)**

Note: Only significant odds ratios are reported. See Table 3A.4 for the full model estimates.

Being retired is associated with higher engagement in social and civic activities than being employed, but lower cultural engagement, lower consumption and lower levels of physical activity. Those who are recorded as ‘other’ (unemployed, permanently sick or disabled, or out of work in order to

look after family members) in terms of economic activity are more likely to belong to the group of people with high social and civic engagement, but more likely to belong to low cultural engagement and consumption groups.

### 3.5.7 Self-rated health

**Figure 3.8. Significant odds ratios of behaviour type, by self-rated health (ref: excellent)**

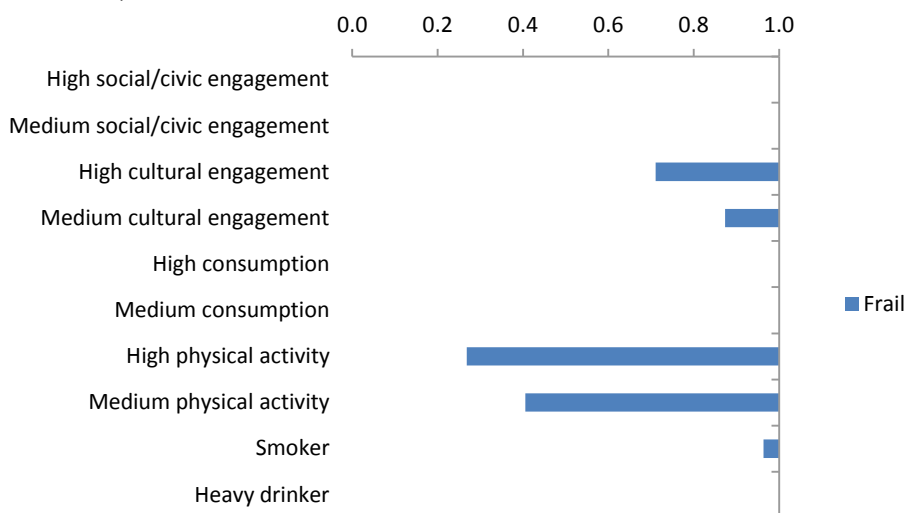

Note: Only significant odds ratios are reported. See Table 3A.4 for the full model estimates.

Health appears to have a strong association with lifestyle behaviours. The poorer a person's self-reported health is, the lower their likelihood of high or medium social and civic or cultural engagement. Poorer health is also associated with low physical activity, and the likelihood of being a smoker increases linearly with decreases in health. Again, a gradient of engagement by level of self-rated health can be observed, with levels of engagement and better health behaviour decreasing as health worsens.

### 3.5.8 Frailty

**Figure 3.9. Significant odds ratios of behaviour type, by being frail (ref: not frail)**

Note: Only significant odds ratios are reported. See Table 3A.4 for the full model estimates.

As might be expected, being frail is associated with a reduced likelihood of belonging to the high or medium cultural engagement groups. Frailty is also associated with lower physical activity and lower likelihoods of smoking.

### 3.5.9 Access to a car

**Figure 3.10. Significant odds ratios of behaviour type, by no car access (ref: has access)**

Note: Only significant odds ratios are reported. See Table 3A.4 for the full model estimates.

Having access to a car is strongly associated with lifestyle behaviours. In each instance of social or civic and cultural engagement, those with no car access are significantly more likely to belong to the group of those with low levels of participation. Low physical activity is also associated with those without access to a car when needed. Smokers are more likely to not have access to a car when needed than those who do not smoke.

### 3.5.10 Access to public transport

**Figure 3.11. Significant odds ratios of behaviour type, by no access to public transport (ref: has access)**

Note: Only significant odds ratios are reported. See Table 3A.4 for the full model estimates.

Having no access to public transport is associated with a significantly reduced likelihood of engaging in high or medium levels of social and civic or cultural activities. A lack of access to public transport is also associated with a reduced likelihood of having lifestyles characterised by high or medium levels of physical activity.

### 3.6 Between-wave individual change in lifestyle behaviours between 2002–03 and 2012–13

This section examines the individual-level longitudinal changes in lifestyle behaviours for each dimension separately for those core members of ELSA who have responded to at least two consecutive waves of data. Table 3.1 shows the level of change in lifestyle behaviours between two consecutive waves over the period 2002–03 to 2012–13. Results are also shown for those who see no change in behaviour between waves and these are stratified according to whether the stable behaviour is classed as ‘low’, ‘medium’ or ‘high’ engagement. Each transition between waves is treated independently, so the measure does not take into account previous transitions, or the length of time spent in each class prior to the change in class membership.

The majority of individuals did not change lifestyle behaviours across transition points. However, there are differences in the typical behaviours associated with each of the dimensions. More than half of the individuals showed consistent low engagement in social and civic activities, yet a similar proportion showed consistent high engagement in cultural activities. Only

**Table 3.1. Lifestyle behaviour changes across transition points, by dimension (% all pooled observations within each behaviour category), 2002–03 to 2012–13<sup>a</sup>**

	Social and civic engagement	Cultural engagement	Consumption	Physical activity	Smoking	Heavy drinking
High to medium	1.69	6.05	0.57	7.37		
High to low	0.59	1.04	1.76	1.55		
Medium to high	2.11	11.93	0.85	6.46		
Medium to low	9.20	3.13	2.74	11.66		
Low to high	0.63	1.64	1.94	1.02		
Low to medium	8.43	6.26	2.80	8.94		
Stable high	0.83	51.38	1.06	10.07		
Stable medium	20.58	14.88	0.50	32.11		
Stable low	55.93	3.69	87.78	20.82		
Total	100	100	100	100		
Stable non-smoking / non-heavy drinking					85.03	70.83
Stable smoking / heavy drinking					11.99	19.21
Stops smoking / heavy drinking					1.98	6.14
Starts smoking / heavy drinking					1.00	3.82
Total					100	100

<sup>a</sup> Changes in consumption are only recorded between 2004–05 and 2012–13.

3.7% of pooled observations showed consistent low cultural engagement across the transition points. The largest changes in social and civic engagement are from medium to low and from low to medium. For cultural engagement, the highest change is observed from medium to high.

The vast majority of people belong to the group of those displaying continuously low consumption behaviour (87.8%). The highest percentages of people changing consumption behaviour are observed among those who move between low and medium consumption behaviour.

Almost one-third of individuals take part in moderate physical activity in all waves, with only just over one in ten people taking part in high activity in all waves. The highest proportion of people changing activity levels is observed among those who move from medium to low activity. The vast majority of individuals are non-smokers, and only 2.0% of the respondents stop smoking across transition points. Almost a fifth of individuals drink daily or almost daily in all waves, and almost twice as many reduce their level of drinking as increase it.

## **3.7 Drivers of change in lifestyle behaviours**

### **3.7.1 Model specification**

This section provides analysis of the drivers of changes in lifestyle behaviours using multinomial logistic regression modelling. The outcomes measures are changes in lifestyle behaviours between subsequent waves (i.e. changes in latent class membership for dimensions of engagement and consumption and changes in smoking, frequency of alcohol consumption and physical activity). The same model is fitted for each of the domains of lifestyle behaviour. The data included in the model are pooled for each transition point between each wave of ELSA (i.e. 2002–03 to 2004–05, 2004–05 to 2006–07, 2006–07 to 2008–09, 2008–09 to 2010–11 and 2010–11 to 2012–13) so that individuals are allowed to have more than one transition point recorded over the five potential transition periods and a longitudinal analysis of change over time can be reported. The longitudinal nature of the analysis is controlled for by measuring covariates that might influence changes in behaviour at baseline.

The model is fitted to include time-varying socio-demographic and socio-economic characteristics measured at the wave before the transition point (for example, age at 2002–03 if we are examining change in behaviour at 2004–05). Inclusion of baseline characteristics allows us to examine their associations with subsequent changes in lifestyle behaviours. In addition, changes of circumstance between waves (i.e. moving into retirement, becoming widowed, becoming frail and losing access to transport) are included as predictors of lifestyle change.

Table 3.2 shows the frequency of these changes in circumstance at each of the transition points.

Between a half and two-thirds of people are retired at any pair of waves across the data period, and this percentage generally increases over time. The

**Table 3.2. Change in employment status, marital status, frailty and access to transport across transition points (%), 2002–03 to 2012–13**

	Waves 1–2	Waves 2–3	Waves 3–4	Waves 4–5	Waves 5–6
<b>Employment status</b>					
Employed at both waves	32.69	29.61	32.36	28.57	23.49
Retired at both waves	56.42	61.19	57.46	61.01	66.82
Becomes retired	5.08	4.36	5.09	5.87	5.89
Starts or increases work	3.49	2.84	2.73	2.60	2.01
Reduces working hours	2.30	2.00	2.36	1.95	1.79
<b>Marital status</b>					
Couple at both waves	72.88	72.21	73.76	75.42	75.03
Single at both waves	4.82	4.78	5.14	5.15	4.96
Separated/divorced at both waves	2.72	2.56	2.63	2.57	2.56
Widowed at both waves	16.65	18.01	16.30	14.58	15.19
Becomes widowed	1.92	1.76	1.29	1.51	1.53
Becomes separated/divorced	0.32	0.22	0.20	0.26	0.29
Becomes a couple	0.69	0.46	0.68	0.51	0.44
<b>Frailty</b>					
Not frail at both waves	66.74	65.87	64.76	63.72	53.45
Frail at both waves	20.21	22.07	22.23	23.86	28.35
Becomes frail	8.28	7.32	8.04	8.69	13.90
Becomes not frail	4.77	4.74	4.97	3.74	4.30
<b>Access to a car</b>					
Access at both waves	78.00	78.56	79.01	79.78	79.06
No access at both waves	12.66	13.93	13.22	12.42	12.33
Loses access	5.93	4.20	4.26	4.58	5.70
Gains access	3.41	3.31	3.51	3.22	2.91
<b>Access to public transport</b>					
Access at both waves	61.51	56.15	53.64	57.96	59.30
No access at both waves	24.56	33.40	32.54	30.24	29.51
Loses access	5.51	6.15	5.44	5.97	6.54
Gains access	8.42	4.30	8.38	5.84	4.65

percentage of people becoming retired between waves increases slightly and the percentage of those who move back into work or increase their working hours decreases over time.

More than two-thirds of respondents are married, cohabiting or in a civil partnership across each transition point and the percentage increases over time. The proportion of people widowed at both waves decreases slightly over time.

The percentage of people who are frail in both waves of the transition point increases from 20% at waves 1–2 to 28% at waves 5–6, and the proportion of people who are not classed as frail at either wave falls from over two-thirds at the first transition point to just over half by the last.

Access to a car and to public transport remains stable across waves. The majority of people have access to a car when needed, and over half of adults

have access to public transport, at each wave of the data. Only a small percentage of people lose transport access at each wave.

### 3.7.2 Changes in lifestyle behaviours by baseline characteristics

#### *Social and civic engagement*

Table 3A.5 presents the model estimates for changes in social and civic engagement conditional on baseline characteristics at each of the transition points. Significant odds ratios are highlighted in bold. Being female is associated with a reduced likelihood of belonging to low social and civic engagement groups at baseline (stable low and low to medium). Being single is associated with a reduced likelihood of remaining in the stable low group but an increased likelihood of belonging to the group that changes from low to high engagement. Being divorced or separated at baseline is associated with the lower engagement groups (stable low, medium changing to low and low changing to high). Being in the highest wealth quintile is associated with belonging to the stable high and high to medium groups, and belonging to any of the wealth quintile categories other than the poorest is associated with a lower likelihood of belonging to the stable low engagement group.

Education level appears to be a key driver of group membership. Figure 3.12 shows the significant odds ratios of social and civic engagement group membership by education level. Higher education levels are associated with membership of the higher engagement groups (stable high, high to medium and medium to high), and lower levels are associated with the lower groups (stable low, high to low, medium to low and low to high or medium).

Health is another key driver of group membership, with poorer baseline health strongly associated with membership of the stable low group, the medium to low group, and both groups that see an increase in engagement from low levels at baseline. Being retired is significantly associated with a lower likelihood of belonging to groups that show low engagement either before or after the transition point.

**Figure 3.12. Significant odds ratios of change in social and civic engagement, by education (ref: low)**

Note: Only significant odds ratios are reported. See Table 3A.5 for the full model estimates.

Frailty is another key predictor of social and civic engagement in later life. Being frail at baseline is associated with an increased chance of moving from high engagement to low or medium, as well as from medium to low. Those who are frail are also more likely to belong to the group of individuals whose engagement levels are continuously low.

Having no access to a car and having no access to public transport are both associated with membership of the stable low engagement group. Having no access to public transport is significantly associated with a decreased likelihood of being able to increase levels of engagement in any manner.

***Cultural engagement***

The estimates from the baseline model showing changes in cultural behaviour are presented in Table 3A.6. Older age is associated with membership of groups that see a decline in cultural engagement, as well as the stable low group. Being female is associated with membership of the stable high engagement group, as well as the groups that move between high and medium engagement. Being single is significantly associated with belonging to the stable low engagement group.

One of the largest drivers of cultural engagement appears to be baseline wealth. Figure 3.13 shows the significant odds ratios for membership of cultural engagement groups on the basis of wealth quintile. Being in higher wealth quintiles is associated with membership of high engagement groups (stable high and moving into and out of high engagement) as well as with significantly lower likelihoods of belonging to any of the groups characterised by low engagement either before or after the transition point.

Higher education level is also associated with membership of the groups that show stable high engagement, or movement into or out of high engagement. Belonging to the ‘other’ category of employment status, which includes people who are unemployed, disabled or caring for family members, is associated with membership of low engagement groups (stable and movement into and

**Figure 3.13. Significant odds ratios of change in cultural engagement, by wealth quintile (ref: poorest)**

Note: Only significant odds ratios are reported. See Table 3A.6 for the full model estimates.

out of low engagement). Self-reported health appears to be another large driver of changes in cultural engagement over time, with better health associated with the high engagement groups (stable and movement into and out of high engagement) and poorer health associated with continuously low engagement. Frailty at baseline is associated with stable low engagement and movements into low engagement. People who have no access to a car when needed are over twice as likely to move from high to low engagement or to belong to the group displaying stable low engagement. They are also almost twice as likely to move from medium engagement to low. Similarly, having no access to public transport at baseline is significantly associated with moving from both high and medium engagement to low, as well as with stable low engagement. Those without car or public transport access are significantly less likely to be able to move from medium levels of engagement to high.

### ***Consumption***

The strongest drivers of consumption behaviour appear to be education and frailty (see Table 3A.7). Those with higher education are less likely to belong to any of the consumption groups that move into or out of lower levels of consumption. Those who are frail at baseline are twice as likely to move from medium consumption into low.

### ***Health behaviour***

Tables 3A.8 and 3A.9 show the results of the baseline model for changes in smoking, drinking and levels of physical activity. Non-smokers at both waves are likely to be older, wealthier and better educated, and less likely to be in poorer health and single, divorced or separated, or widowed. Wealth is a large driver of stopping smoking, with a gradual increase in the likelihood of stopping as wealth quintile increases.

Moving from daily or almost daily drinking to less than daily drinking, compared with continuous heavy drinking, is less likely among older people than those aged 50–59. Being female is significantly associated with less frequent drinking and less stable patterns of drinking (i.e. women are more likely to either reduce or increase alcohol consumption than men). All health categories have an increased likelihood of reducing drinking compared with those in excellent health.

Age is a key driver of change in physical activity. The oldest age groups are more likely to belong to groups that move to low activity or are low at the beginning of the transition point. Wealth is another important driver, with higher wealth associated with stable levels of high physical activity and movement between high and medium activity. The strongest driver of change in physical activity, however, is baseline health. Those with the poorest health are ten times more likely to belong to the group of people who remain in low activity across the transition point and between two and three times more likely to belong to the groups with movement into and out of low activity. Baseline levels of frailty are similarly associated with the activity groups showing movement into and out of the low category, and those who are frail are less likely to belong to the group with stable high activity.

### **3.7.3 Changes in life circumstances and changes in lifestyle behaviour**

This section discusses the results of the logistic regression models when changes in employment, partnership, frailty and access to a car and to public transport are included in the model. The results are presented in Tables 3A.10 to 3A.14. The baseline effects remain consistent for each model after accounting for changes in individual circumstances and are not shown in the tables.

#### ***Social and civic engagement***

Becoming retired is associated with an increased likelihood of moving from low social and civic engagement to medium and a decreased likelihood of remaining in the low engagement group.

Those who become widowed are over twice as likely as couples to move from medium engagement to high and are likely to move from low to medium engagement. However, they are also more likely to remain in the low engagement group or to move from medium to low engagement after the change in relationship status.

Frailty is the main driver of changes in social and civic engagement. Those who become frail are more likely to move from medium to low engagement and are over twice as likely to move from high to low engagement. Additionally, being continuously frail is associated with all possible reductions in engagement.

Having no access to a car when needed both before and after a transition point, or only before or only after, is associated with continuously low social and civic engagement. Losing car access, as well as continuous lack of car access, is also associated with declines in engagement from high and medium to low.

The association between changes in public transport and lifestyle behaviours is less marked than that between changes in car access and lifestyle behaviours. Continuous lack of public transport access is associated with declines from high engagement to low or medium, and both continuous lack of access and loss of access are associated with belonging to the group of people displaying continuously low-level social and civic engagement.

#### ***Cultural engagement***

Changes in employment situations have little influence on cultural engagement. Being retired at both waves of the transition point is associated with an increased likelihood of moving from medium to low engagement, and a decreased likelihood of moving from low to high engagement.

Those who become widowed are almost three times as likely to move from low engagement to high engagement. Being single at both waves is associated with stable low engagement and movement from low to medium engagement.

Changes in frailty are a key driver of changes in cultural engagement. Figure 3.14 shows the significant odds ratios for the likelihood of group membership according to changes in frailty status. Becoming frail between waves is associated with an increased likelihood of moving from either high or medium

**Figure 3.14. Significant odds ratios of change in cultural engagement, by changes in frailty (ref: not frail at both waves)**

Note: Only significant odds ratios are reported. See Table 3A.11 for the full model estimates.

engagement to low. The same pattern exists for being continuously frail, although these people are also more likely to have been in low engagement across the transition point.

Access to transport also drives changes in cultural engagement. Having a continuous lack of access to a car is associated with moving into low engagement from medium and high levels as well as with consistent low engagement. Changes in access to public transport predict changes in cultural engagement less than continuously not having access to public transport, which is again significantly associated with membership of the stable low engagement group and of the groups that move into low engagement from high and medium levels.

***Consumption***

None of the predictor variables included in this analysis appears to show strong patterns in predicting changes in consumption. People who become retired are over twice as likely as the reference group of workers to move from medium to lower consumption and almost twice as likely to remain in low consumption across transition points. Being continuously retired is associated with an increased likelihood of belonging to groups that move into low consumption and of having stable low consumption.

People who are single or divorced at both points of the transition period are significantly more likely than those who are married, in a civil partnership or cohabiting to remain in the low consumption group.

People who have no access to public transport both before and after a transition point, or who lose access to public transport, are more likely to belong to the group of people displaying continuously lower levels of consumption.

### ***Health behaviour***

Being retired both before and after a transition point is associated with a decreased likelihood of stopping smoking compared with people who are continuously employed, whilst either re-entering work (from any circumstance) or increasing hours worked is associated with a higher likelihood of stopping smoking. Becoming frail between waves is associated with a significantly increased likelihood of stopping smoking. None of the changes to individual circumstances is significantly associated with changes to drinking behaviour, apart from becoming a couple being associated with an increased likelihood of drinking heavily at both waves.

As might be expected, frailty is the largest driver of changes in physical activity in later life. Those who become frail between waves are over twice as likely to change from high to low or medium to low physical activity. Those who lose access to a car when needed, as well as those who continuously have no access to a car when needed, are significantly more likely to move from medium activity to low or to belong to the group of people displaying consistently low levels of physical activity. Becoming retired is associated with moving from high and medium activity to low. This is likely to reflect the loss of physical activity among people retiring from manual work.

## **3.8 Conclusions**

Previous research has suggested positive lifestyle behaviours in later life comprise part of the healthy ageing process. Conversely, lower engagement in social and cultural activities and unhealthy behaviour, such as low levels of physical activity, have been linked to poorer ageing outcomes. The research presented within this chapter has shown that lifestyle behaviours have remained relatively stable between 2002–03 and 2012–13, but that there was wide variation in these stable types of behaviours that older people were engaged in. Around two-thirds of older adults had low levels of social and civic engagement yet approximately the same number had high levels of cultural engagement. Very few adults aged over 50 smoked or drank heavily. Over the period 2002–03 to 2012–13, over a fifth of older adults changed their level of social and civic engagement at some point, almost a third changed their level of cultural engagement and a tenth changed their level of consumption. Half of those making changes to social and civic engagement and consumption saw decreases in activity, whilst this figure was a third among those changing levels of cultural activity. It should therefore be noted that ageing is associated with increases in healthy lifestyle behaviours as well as reductions.

Older age appeared to be associated with a decreased likelihood of belonging to all high or medium lifestyle behaviour groups. With the exception of high social and civic engagement, these associations remained significant after accounting for other age-related factors, such as being retired, being widowed and being frail. This suggests an association exists between growing older and lower levels of participation in lifestyle behaviours that may affect the healthy ageing process.

Being married, in a civil partnership or cohabiting appeared to be associated with higher levels of social and civic engagement but lower levels of cultural engagement. Higher levels of consumption were observed among those who were single and never married, and being divorced or separated and being widowed were associated with increased participation in high and medium levels of physical activity. So, whilst being in a relationship may be protective of certain lifestyle behaviours, it appears to have the opposite association for others. This also suggests that being married, in a civil partnership or cohabiting is associated with an increase in social networks, subsequently leading to increased involvement in societal activities. Becoming widowed was associated with both increases and decreases in levels of social and civic engagement, but an increase in cultural engagement.

Wealth showed strong graded relationships with all types of lifestyle behaviours. Higher levels of wealth were consistently associated with higher engagement in social and civic activities, higher engagement in cultural activities, higher patterns of spending and higher participation in high levels of physical activity. Daily or almost daily drinking was also associated with higher wealth, but we were not able to quantify the amount consumed each day or the type of alcoholic beverage consumed. Smoking was the only activity linked to lower wealth. In terms of healthy lifestyle behaviours, a strong pattern was observable in that likelihood of engagement increased with every wealth quintile. This suggests low engagement in favourable lifestyle behaviours in older age is strongly linked to wealth and that attention must be paid to those in lower wealth groups, who may be at risk of isolation or of participation in unhealthy lifestyle choices. Education level followed a similar pattern to wealth, with higher engagement consistently noticeable among those who left education at older ages. This places participation in lifestyle behaviours within a life-course perspective, with better educational attainment likely to lead to higher wealth throughout adult life and therefore a healthier ageing process in later life.

Health was another important indicator of engagement. In each instance, with the exception of smoking, the worse an individual's health was, the less likely they were to engage in any of the favourable lifestyle behaviours (better health was associated with higher alcohol consumption, but the lack of knowledge about the amount or type of drink consumed is problematic in meaningfully interpreting this result).

Becoming retired was associated with an increase in social and civic engagement and a reduced likelihood of consistently low social and civic engagement. Being retired was associated with membership of the higher social and civic engagement groups. This might be because the activities carried out within this dimension, such as attending an organisation or participating in voluntary work, might take up more time than other activities and therefore are more commonly done after giving up work. With the exception of social and civic participation, belonging to the 'other' group of the employment status categories was associated with lower levels of engagement in all lifestyle behaviours. Again, this suggests those who are in unfavourable situations, such as being unemployed, disabled or caring for family members, are at high risk of detachment from society and of adopting unhealthy lifestyles.

Frailty was one of the strongest predictors of change in lifestyle behaviours. Becoming frail was consistently associated with drops in levels of both social and civic and cultural engagement. Consistent frailty was similarly associated with reductions in engagement and membership of the continuously low engagement groups.

No transport access and loss of transport access were associated with reductions in and continuously low levels of social and civic engagement and cultural engagement. Again, this highlights the importance of ensuring older people are able to connect themselves to the wider community in order to live favourable lifestyles. This may be especially true for those who do not use public transport because they cannot afford it or are physically incapable of doing so and are at high risk of detachment from society.

Policymakers might focus on accessibility of social, civic and cultural engagement, and ensure those at the highest risk of detachment from societal activities are able to participate in them. Policy should be targeted at those with the lowest levels of wealth and health, including those who are frail and becoming frail, in order to lessen the likelihood of movement into lower levels of engagement and unhealthier lifestyle choices, such as low-level physical activity. Public transport should be made accessible for those who struggle to use it and subsequently may not be able to engage in their preferred societal activities or lifestyle behaviours.

## 4. Trends in obesity among older people in England

**Paola Zaninotto** *University College London*

**Sarah Jackson** *University College London*

**Marta Jackowska** *University College London*

**Sally Bridges** *NatCen Social Research*

**Andrew Steptoe** *University College London*

The findings in this chapter explore changes in obesity, as measured by body mass index (BMI) and waist circumference, over an eight-year period, between wave 2 (2004–05) and waves 4 (2008–09) and 6 (2012–13) in ELSA respondents aged 52 and over.

Key points arising from this chapter are:

- At wave 2 (2004–05), the average BMI was 29 kg/m<sup>2</sup> for men and for women and this increased on average over the next eight years by a similar margin in men and women (0.5 kg/m<sup>2</sup>). The degree of change in BMI over time was not related to wealth.
- The average waist circumference at wave 2 was 102.1 cm for men and 92.5 cm for women and it increased over eight years by 1.6 cm among men and 1.4 cm among women. The increase in waist circumference over time was related to low wealth for men but not for women.
- The prevalence of men and women who were obese according to either BMI or waist circumference increased significantly over time; women were more likely than men to be obese (as defined by BMI) and centrally obese (measured by waist circumference) at each time point.
- Retirement did not have a significant impact on change in BMI or waist circumference overall, with similar increases over time observed in individuals who retired and those who did not retire. However, retirement was associated with greater increases in BMI and waist circumference over time in people who retired from standing and physically active occupations, and retirement at wave 6 was also associated with greater increases in waist circumference for those who were less wealthy.
- The prevalence of obesity in men and women recorded over three waves (2004–05, 2008–09 and 2012–13) was highest among those aged 52–59.
- In both sexes, the prevalence of never being obese was highest among those in the richest wealth quintile, and wealthy women were more likely than wealthy men never to be obese over the eight-year study period.
- People with intermediate levels of measured walking speed (0.87–1.02 m/s) and those with slow walking speed (below 0.87 m/s) were more

likely to have sustained obesity (as measured by both BMI and waist circumference) across waves than people with fast walking speed (above 1.02 m/s).

- Steep declines in walking speed (−0.102 to −0.32 m/s) and in hand grip strength (−16.2 to −4.6 kg) over waves were associated with increased odds of sustained obesity as measured by BMI.
- Older people with poor blood glucose control (glycated haemoglobin, HbA1c  $\geq 58$  mmol/mol) were more likely to be persistently obese and to have a raised waist circumference than were people without diabetes or those with low HbA1c.
- Increased levels of HbA1c were also associated with an increased risk of sustained obesity and central obesity across waves, independently of lifestyle factors, diabetes and other adjustment variables.
- In the subset of ELSA respondents who had physical activity measured objectively with accelerometers, both obese and non-obese respondents spent an average of between 40 and 50 minutes of each waking hour being sedentary, but those who were obese spent more time sedentary and less time carrying out light or moderate/vigorous activity than their non-obese counterparts.
- When physical activity was defined by self-report, we found that nearly 43% of respondents who reported sedentary activity were obese and 65% were centrally obese.
- When physical activity was assessed objectively, we found that 50% of sedentary respondents were classified as obese and 52% as centrally obese.
- In regression analyses adjusted for confounding variables, none of the self-reported physical activity levels was associated with obesity (as measured by BMI), while those carrying out only light or sedentary physical activity as measured objectively were significantly more likely to be obese than those engaging in moderate/vigorous objective physical activity.
- Sedentary behaviours assessed either by self-report or by objective measures were associated with increased odds of central obesity, with effects being stronger for objective measures.

## **4.1 Introduction**

Over the past 30 years, there has been a marked increase in the number of overweight and obese older adults, due to increases both in the total number of older people (Office for National Statistics, 2012) and in the proportion who are overweight (Health Survey for England, 2010).

Repeat cross-sectional data from the Health Survey for England and the National Health and Nutrition Examination Survey (NHANES) in the US reveal that while rates of obesity are rising across all age groups, there is a trend for greater increases in prevalence among older (55 and over) than among younger adults, reaching 32% (vs. 23%) in England (Health Survey for England, 2010) and 40% (vs. 35%) in the US in 2010 (Flegal et al., 2012).

In a study published in *The Lancet*, Wang and colleagues (2011) used data from the Health Survey for England (since 1993) and NHANES (since 1988) in a simulation model to predict future increases in obesity prevalence in the UK and the US. Based on recent trends, and taking into account the ageing populations in both countries, they projected that there would be an additional 11 million obese adults in the UK by the year 2030, of whom 3.3 million would be aged  $\geq 60$  years, and an extra 65 million in the US, of whom 24 million would be aged  $\geq 60$  (Wang et al., 2011, figure 1.6).

Wang et al. (2011) also modelled the likely economic consequences of a sustained rise in obesity prevalence over the next 20 years in the US and the UK. Their projections showed that if past trends continue, healthcare costs are likely to rise by \$48–\$66 billion each year in the US and by £1.9–£2 billion each year in the UK. Over the next two decades, this equates to a 13–16% increase in the annual costs of obesity-related diseases in the US, of which 4% will be attributable to population ageing alone, and a 24–25% increase in the UK, of which 10% will be attributable to ageing alone. A rise of this nature in the UK poses a significant threat to the future affordability of the NHS (Wanless, 2004).

For the older population, carrying excess weight comes with additional health risks. The prevalence of many of the medical complications related to obesity increases with advancing age. Approximately 80% of older adults have at least one chronic health condition, and 50% have two or more (Centers for Disease Control and Prevention, 2003). Obesity also has significant functional implications for older people, because it can worsen the age-related decline in physical function. Among older men and women, excess body fat mass and high BMI are positively associated with physical dysfunction and disability (Davison et al., 2002) and strongly predict decline in functional status and future disability (Jensen and Friedmann, 2002).

The next section of this chapter gives details of our sample and the measures and definitions that we use. In Section 4.3, we describe changes over eight years in BMI and waist circumference using three waves of anthropometric measures (wave 2, wave 4 and wave 6). Section 4.4 investigates the impact of an important experience for many people in their later years – namely, retirement – on changes in BMI and waist circumference. We then explore, in Section 4.5, the relationship between duration of obesity and changes in physical function (lower limb mobility and muscle strength) and health (glycated haemoglobin, HbA1c). Lastly, using a subsample of ELSA respondents who participated in a study of objective physical activity, Section 4.6 explores the relationships between obesity and self-reported and objective physical activity.

## **4.2 Methods**

### **4.2.1 Sample**

In Sections 4.3, 4.4 and 4.5, the sample comprised 4,894 members, aged 52 and over, of the original ELSA cohort (core members) who had participated in the study and had a nurse visit in wave 2 (2004–05), wave 4 (2008–09) and wave 6 (2012–13).

The cross-sectional analyses described in Section 4.6 used exclusively data from a subsample of 244 ELSA respondents who participated in a study of objective physical activity and had a nurse visit in wave 6.

### **4.2.2 Obesity measures**

Height, weight and waist circumference were measured during the nurse visits carried out in waves 2, 4 and 6.

#### ***Height***

Height was measured using a portable stadiometer. Respondents were asked to remove their shoes. One measurement was taken with the respondent stretching to the maximum height and the head in the Frankfort plane.<sup>1</sup> The reading was recorded to the nearest millimetre.

#### ***Weight***

Weight was measured using a portable electronic scale. Respondents were asked to remove their shoes and any bulky clothing. A single measurement was recorded to the nearest 0.1 of a kilogram. Respondents who weighed more than 130 kg were asked for their estimated weights because the scales are inaccurate above this level (approximately 0.2% of people at each nurse visit). These estimated weights were included in the analysis.

#### ***Waist circumference***

The waist was defined as the midpoint between the lower rib and the upper margin of the iliac crest. Waist circumference was measured using a tape with an insertion buckle at one end. The measurement was taken twice, using the same tape, and was recorded to the nearest even millimetre. Those whose waist circumference measurements differed by more than 3 cm had a third measurement taken. The mean of the two valid measurements (the two out of the three measurements that were closest to each other, if there were three measurements) were used in the analysis.

### **4.2.3 Definitions**

#### ***Obesity***

Body mass index (BMI) is a widely-accepted measure of weight for height and is defined as weight in kilograms divided by the square of the height in metres (kg/m<sup>2</sup>). BMI was calculated for all those respondents for whom both a valid height measurement and a valid weight measurement were recorded.

Applying the classification of the World Health Organisation (2000) and the National Institute of Health and Clinical Excellence (2006), we defined people as being obese if they had a BMI  $\geq 30$  kg/m<sup>2</sup>.

---

<sup>1</sup> The Frankfort plane is an imaginary line passing through the external ear canal and across the top of the lower bone of the eye socket, immediately under the eye. This line must be parallel with the floor. This gives the maximum vertical distance from the floor to the highest point of the skull.

### ***Central obesity***

BMI does not distinguish between mass due to body fat and mass due to muscular physique and does not take account of the distribution of fat. It has therefore been postulated that waist circumference may be a better measure than BMI or waist-to-hip ratio (World Health Organisation, 2000) for identifying those with a health risk from their body shape. As people age, the fat distribution changes considerably and abdominal fat tends to increase. Therefore waist circumference can be considered an appropriate indicator of body fatness and central fat distribution among the elderly. Using sex-specific cut-offs (Flegal, 2007), we defined central obesity as waist circumference  $\geq 102$  cm for men and  $\geq 88$  cm for women.

#### **4.2.4 Classificatory variables, social covariates and outcome measures**

Three main classificatory variables were employed to analyse the obesity measures: age, sex and wealth. Age was coded into four groups: 52 to 59 years, 60 to 69 years, 70 to 79 years, and 80 years or older. (There was no refreshment sample in 2004–05, so the youngest participants, who were 50 in wave 1, had already been involved in the study for two years and were aged 52 in wave 2.)

Total wealth (excluding regular pension payments, but including lump sums from private pensions that had already been received but not yet consumed) was defined as financial wealth, physical wealth (such as business wealth, land or jewels) and housing wealth (primary and secondary residential housing wealth), minus debts. Wealth was categorised into five equal groups of net total non-pension wealth measured at benefit unit level (a benefit unit is a couple or single person along with any dependent children they might have). The longitudinal analyses employed wealth data from 2004–05 (wave 2) while the cross-sectional cross-wave analyses used wealth data from 2012–13 (wave 6).

#### **4.2.5 Analysis**

##### ***Change over time in BMI and waist circumference***

To estimate change over time in BMI and waist circumference, we used latent growth curve (LGC) methodology (Meredith and Tisak, 1990; Duncan and Duncan, 1995). Latent factors representing intercept (baseline status) and slope (rate of change) components are extracted from the three observations of the variable of interest across time, here identified as wave 2 (baseline), wave 4 and wave 6. The model fit suggested that the baseline estimates and the rate of change were perfectly close to the observed data. The advantage of using LGC methodology is that missing data can be handled using Full Information Maximum Likelihood estimation, which computes parameter estimates on the basis of all available data under the assumption that data are missing at random (Enders and Bandalos, 2001). For the purpose of this chapter, we selected respondents who had at least two out of three valid BMI or waist measurements and consequently the third measurement was estimated using Full Information Maximum Likelihood estimation. The estimations resulted in longitudinal samples of 2,956 individuals for BMI and of 4,494 individuals for waist circumference.

### Age standardisation

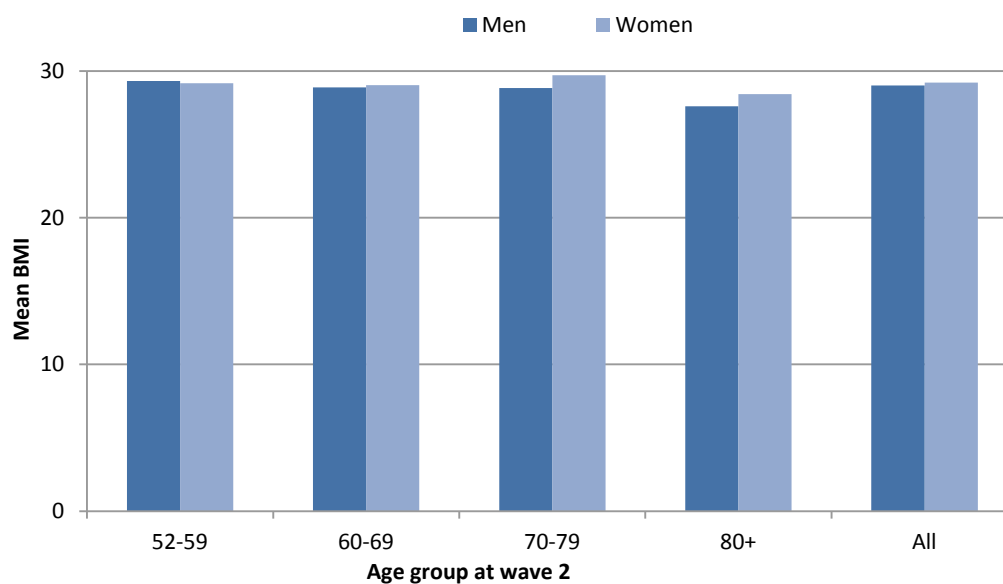

Age standardisation has been used in all tables in Sections 4.3, 4.4 and 4.5 in which age is not included as a break variable. Age standardisation removes the effect of differences in age distributions from comparisons between groups. Direct standardisation was applied for both sexes, with the standards being the age distribution of the whole ELSA sample at wave 2.

## 4.3 Changes in anthropometric measures by age group, sex and wealth

### 4.3.1 Changes in BMI by age group and sex

Figure 4.1 shows that the average BMI at wave 2 was 29.0 for men and 29.2 for women, indicating that, on average, both men and women were overweight at wave 2. There was no significant relationship between age group and average BMI for men or women at wave 2 ( $p=0.073$  and  $p=0.153$ , respectively). Looking at change over eight years (Figure 4.2), average BMI increased by a similar margin in men and women (0.48 and 0.49, respectively). The change in average BMI over time differed across age groups for both men and women ( $p<0.001$  and  $p<0.0005$ , respectively). For men, those aged 52–59 at wave 2 had the greatest increase in BMI (0.67), followed by those aged 60–69 (0.48). Among older age groups, there was no significant change over time in average BMI. The same pattern was observed among women, with those aged 52–59 having the greatest average increase in BMI, followed by those aged 60–69 (0.73 and 0.50, respectively). In the oldest age group, there were signs that, on average, women’s BMI was reducing, though this reduction was not statistically significant and the sample size was much smaller here than in other age groups.

**Figure 4.1. Mean BMI at wave 2, by age group and sex**

**Figure 4.2. Change in mean BMI over eight years (2004–05 to 2012–13), by age group and sex**

### 4.3.2 Changes in BMI by wealth and sex

At wave 2, average BMI varied with wealth for both men and women ( $p < 0.0005$  for both men and women). Those in the lowest wealth quintile had the highest BMI, on average, and BMI decreased with each increasing wealth quintile. Among men, average BMI ranged from 30.1 in the lowest wealth quintile to 28.1 in the highest wealth quintile (Table 4A.1 in the appendix to this chapter). The pattern was the same for women but with a steeper gradient, from 31.3 in the lowest wealth quintile to 26.7 in the highest.

The degree of change in BMI over time was not related to wealth for either men or women ( $p = 0.697$  and  $p = 0.186$ , respectively). An increase of between 0.4 and 0.5 in average BMI was seen across all wealth quintiles for men (Table 4A.1). Among women, there were increases of between 0.3 and 0.5 across all wealth quintiles except for the fourth, where the change of 0.2 over time was not significant.

### 4.3.3 Changes in waist circumference by age group and sex

At wave 2, the average waist circumference was 102.1 cm for men and 92.5 cm for women (Figure 4.3). There was no significant relationship between age group and average waist circumference at wave 2 for men or women ( $p = 0.266$  and  $p = 0.054$ , respectively). Over eight years (Figure 4.4), average waist circumference increased by 1.6 cm among men and 1.4 cm among women. Average waist circumference in men and women increased among all age groups over time ( $p < 0.05$  for both men and women). The size of the increase differed by age group, with the youngest age group having the greatest average increase and the oldest age group having the smallest. Among men, the increase in average waist circumference ranged from 1.7 cm among 52- to 59-year-olds down to 0.9 cm among those aged 80 or over. The same pattern existed for women, with the greatest increase in average waist circumference, of 1.5 cm, seen in those aged 52–59 and the smallest, of 0.9 cm, in those aged 80 and over (Figure 4.4)

**Figure 4.3. Mean waist circumference at wave 2, by age group and sex****Figure 4.4. Change in mean waist circumference over eight years (2004–05 to 2012–13), by age group and sex**

#### 4.3.4 Changes in waist circumference by wealth and sex

Table 4A.2 in the appendix shows that at wave 2, average waist circumference differed depending on wealth for both men and women ( $p < 0.001$  for both men and women). Those in the lowest wealth quintile had the largest waist circumference, on average, and waist circumference decreased with each increasing wealth quintile. Among men, the average waist circumference ranged from 105.3 cm in the lowest wealth quintile to 100.0 cm in the highest wealth quintile. The pattern was the same for women but with a steeper gradient, from 96.4 cm in the lowest wealth quintile to 89.3 cm in the highest.

The increase in waist circumference over time was related to wealth for men but not for women ( $p < 0.01$  and  $p = 0.745$ , respectively). Among men, the level of increase in waist circumference over time was greatest in the lowest income quintile and reduced with each increasing wealth quintile apart from the

highest. Men in the lowest income quintile had an increase in average waist circumference of 1.9 cm, compared with an increase of 1.5 cm in the highest wealth quintile (Table 4A.2). There was no such pattern among women, where a similar increase of between 1.2 and 1.4 cm in average waist circumference was seen across all wealth quintiles.

## **4.4 Changes in obesity and retirement**

In this section, we explore the impact of retirement on changes in BMI and waist circumference across waves 2, 4 and 6, and we test interactions with occupation and wealth. We also investigate whether the association differs by sex and level of physical activity in the workplace. Previous studies have shown that retirement is associated with changes in anthropometry (Chung et al., 2009; Nooyens et al., 2005); however, the relationship varies according to the type of occupation and wealth of individuals.

### **4.4.1 Methods**

Retirement was defined on the basis of self-reported employment status. Those who reported being in paid employment at wave 2 and reported being completely retired at wave 4 were defined as having retired at wave 4. Likewise, those who reported being in paid employment at wave 4 and being completely retired at wave 6 were defined as having retired at wave 6. We compared these two categories with the rest of the sample, i.e. those who were still in paid employment, those who were always retired and those permanently unable to work or looking after home. We did not analyse those who defined themselves as being permanently unable to work or looking after home at one wave and then retired at another wave, since their life style is less likely to have changed. We also compared people who had retired from sedentary jobs, jobs involving standing, and physically active manual occupations.

### **4.4.2 Mean BMI and waist circumference by wave, sex and retirement status**

Figure 4.5 shows mean BMI values at wave 2, wave 4 and wave 6, by retirement status and sex. In each group, mean BMI increased consistently over time. Among men, there was little difference in the change in BMI over time by retirement group. However, among women, there was a slightly greater increase in BMI between waves in the groups who retired at wave 4 and wave 6 than in the group who did not retire at either of these waves. In the groups who retired, the increase in mean BMI over time was larger for women than men, but it was roughly the same for the two sexes in the group who did not retire.

Figure 4.6 shows mean waist circumference measurements at wave 2, wave 4 and wave 6, by retirement status and sex. Consistent with the data for BMI, weight circumference increased over time in all groups. However, there did not appear to be a differential change by retirement status in women as there was for BMI, with changes appearing consistent across all retirement groups in both sexes.

**Figure 4.5. Mean BMI at each wave, by retirement status and sex**

Note: 'Retired W4' indicates those who retired at wave 4. 'Retired W6' indicates those who retired at wave 6. 'Other' indicates those who did not retire from paid employment at wave 4 or wave 6. Age-standardised means.

**Figure 4.6. Mean waist circumference at each wave, by retirement status and sex**

Note: 'Retired W4' indicates those who retired at wave 4. 'Retired W6' indicates those who retired at wave 6. 'Other' indicates those who did not retire from paid employment at wave 4 or wave 6. Age-standardised means.

Mean changes in BMI and waist circumference between waves 2 and 6 are shown by retirement status in Table 4A.3. BMI increased by  $0.34 \text{ kg/m}^2$  on average in the group who retired at wave 4, by  $0.28 \text{ kg/m}^2$  in the group who retired at wave 6 and by  $0.25 \text{ kg/m}^2$  in the group who did not retire at either of these waves. Respective increases in waist circumference by group were 0.83 cm, 0.81 cm and 0.73 cm. Regression models showed no significant effect of retirement at wave 4 or wave 6 on change in BMI or waist

circumference between waves 2 and 6 (Table 4A.4), indicating that retirement did not have a significant impact on BMI or waist circumference.

The effect of retirement on anthropometry did not differ by sex; neither men nor women who retired experienced a differential change in either BMI or waist circumference compared with those who did not retire (results not shown).

#### **4.4.3 Changes in BMI and waist circumference by retirement status and wealth**

Table 4A.5 presents mean changes in BMI and waist circumference over time by retirement status and wealth. There was no significant interaction between retirement at wave 4 and wealth for changes in BMI or waist circumference, nor was there a significant interaction between retirement at wave 6 and wealth for changes in BMI (Table 4A.6). However, the interaction between retirement at wave 6 and wealth was significant for waist circumference (Table 4A.6), with a greater increase in waist circumference in the retirement group than in the group who did not retire among those in the lower four quintiles of wealth (1<sup>st</sup> (poorest) quintile: 0.99 vs. 0.75 cm; 2<sup>nd</sup> quintile: 0.86 vs. 0.79 cm; 3<sup>rd</sup> quintile: 0.95 vs. 0.75 cm; 4<sup>th</sup> quintile: 0.88 vs. 0.69 cm) but a smaller increase in the retirement group among those in the richest quintile (0.52 vs. 0.69 cm).

#### **4.4.4 Changes in BMI and waist circumference by retirement status and level of physical activity in the workplace**

Table 4A.7 reports mean changes in BMI and waist circumference over time by retirement status and level of physical activity in the workplace prior to retirement. The interaction between retirement at wave 4 and physical activity in the workplace was significant for BMI and waist circumference (Table 4A.8). Those who retired from sedentary jobs had a smaller increase in BMI than those who did not retire (0.10 vs. 0.33 kg/m<sup>2</sup>), whereas those who retired from standing or physical jobs had a larger increase than those who did not retire (standing: 0.44 vs. 0.26 kg/m<sup>2</sup>; physical: 0.51 vs. 0.37 kg/m<sup>2</sup>). Changes in waist circumference followed the same pattern across groups (Table 4A.7). There was no significant interaction between retirement at wave 6 and physical activity in the workplace for either BMI or waist circumference (Table 4A.8).

#### **4.4.5 Conclusions**

In this section, we have found that retirement did not have an overall significant impact on change in BMI or waist circumference, with similar increases over time observed in individuals who retired and those who did not retire. Results did not differ according to sex, although there were significant interactions with wealth and level of physical activity in the workplace. Retirement was associated with greater increases in BMI and waist circumference over time in people who retired from occupations involving standing and physical work than those who retired from sedentary jobs. Retirement at wave 6 was also associated with greater increases in waist circumference for those who were less wealthy. These findings are consistent with previous studies that compared changes in body weight, BMI and waist

circumference by type of occupation and wealth (Chung et al., 2009; Nooyens et al., 2005) and indicate that retiring from more active jobs is associated with weight gain. Having a physically demanding job did not protect people from weight gain after retirement; indeed, we observed the opposite pattern.

## **4.5 Duration of obesity and health**

This section addresses the question of whether duration of obesity (general and central obesity) over eight years is associated with changes in physical function (lower limb mobility and muscle strength) and health (glycated haemoglobin-HbA1c). Descriptive analyses are presented first, followed by logistic regression models for the association between duration of obesity and changes in physical function and health.

### **4.5.1 Methods**

#### ***Duration of obesity and central obesity***

Duration of obesity and central obesity was defined as the number of occasions across the three waves of anthropometric measurement (never, for one wave, for two waves, for three waves) on which respondents were obese (BMI  $\geq 30$ ) or centrally obese (waist circumference  $\geq 102$  cm for men and  $\geq 88$  cm for women). For simplicity, in the regression analysis the duration of obesity and central obesity variables were recoded as 0 for ‘never or for one wave’ and 1 for ‘for two or three waves’.

#### ***Physical function and health variables***

We used gait speed (in metres per second, m/s) and hand grip strength as objective measures of physical function. Gait speed is known to be a strong predictor of incident disability (Guralnik et al., 2000) and mortality (Cooper et al., 2010). A lower gait speed is a sign of impaired physical functioning. The gait speed test was administered only to respondents aged 60 and over. It involved them walking twice a distance of 8 feet at their usual pace from a standing start. Gait speed was calculated by dividing distance by the mean time of the two walks (or a single time measurement in the case of there being no second valid time measurement) and was computed only for participants who performed the test without the use of walking aids or other help. The grip strength test is a measure of upper body strength; it is known to be a predictor of disability (Rantanen et al., 1999) and mortality (Cooper et al., 2010). The test was given to all respondents who were willing to take it, with no upper or lower age limits, but with certain exclusions on safety grounds (respondents were excluded if they had swelling or inflammation, severe pain or a recent injury, or if they had had surgery to the hand in the preceding six months). If there was a problem with only one hand, measurements were taken using the other hand. After adjusting the gripometer (grip gauge) to suit the respondent’s hand and positioning the respondent correctly, the respondent was asked to squeeze the gripometer as hard as they could for a couple of seconds. Three values were recorded for each hand, starting with the non-dominant hand and alternating between hands. Any measurements carried out incorrectly were not included. The gripometer used was the ‘Smedley’s for Hand’ Dynamo Meter, scale 0–100 kg.

Glycated haemoglobin (HbA1c) was used as an objective measure of health. HbA1c reflects time-averaged blood glucose during the previous 8–12 weeks, and it is often used as a diagnostic test for diabetes. Blood samples were taken from willing ELSA core members, except those who had a clotting or bleeding disorder (e.g. haemophilia or low platelets), had ever had a fit, were not willing to give their consent in writing or were currently on anticoagulant drugs (e.g. warfarin therapy). Blood samples were analysed at the Royal Victoria Infirmary laboratory in Newcastle.

In wave 6, HbA1c was quantified using IFCC units (mmol/mol). In wave 2 and wave 4, we measured HbA1c using the previously recommended DCCT % units. The latter can be converted to IFCC mmol/mol using the following formula:

$$\text{mmol/mol} = (\% - 2.15) \times 10.929.$$

### ***Change over time in physical function and health***

Change over time in physical function and health was estimated using the latent growth curve methodology described in Section 4.2.5. Wave 2 average gait speed and hand grip strength values were grouped into tertiles, while for HbA1c the following cut-offs were used:

- <48 mmol/mol (6.5%): no diabetes or good control;
- 48–58 mmol/mol (6.5%–7.5%): target range for those with diabetes; indicates diabetes;
- $\geq$ 58 mmol/mol (7.5%): poor blood glucose control.

Changes over time in gait speed, hand grip strength and HbA1c were grouped into tertiles.

### ***Covariates***

A set of covariates from wave 2 were selected as adjustment for the regression models. These included age, sex, cohabitation status (defined as cohabiting or not with a partner), coronary heart disease (CHD), diabetes, limiting long-standing illness, physical activity (light/moderate/high vs. low/sedentary), frequency of alcohol consumption (less than daily vs. daily), smoking status (never smoked/ex-smoker vs. current smoker).

## **4.5.2 Duration of obesity and central obesity by age, sex and wealth**

Figure 4.7 shows the prevalence of men and women recorded as being obese or centrally obese at each wave. At wave 2, 25.9% of men were obese; the prevalence increased to 27.7% at wave 4 and to 28.2% at wave 6. Among women, the prevalence increased from 30.7% at wave 2 to 33.5% at wave 4 and to 33.9% at wave 6. The gender difference in the prevalence of obesity was statistically significant at each time point ( $p < 0.001$ ).

The prevalence of men who were obese according to waist circumference increased over time from 45.9% in wave 2 to 50.3% at wave 4, and then it slightly decreased at wave 6 to 48.9% (non-significant); similarly, the prevalence of women who were obese according to waist circumference

**Figure 4.7. Prevalence of obesity and central obesity, by wave and sex**

Note: Obesity defined as BMI  $\geq 30$ . Central obesity defined as waist circumference  $\geq 102$  cm for men and  $\geq 88$  cm for women. Age-standardised figures.

increased from 55.8% in wave 2 to 62.0% in wave 4, and then it decreased to 60.9% (non-significant). Women were more likely than men to have raised waist circumference at each time point ( $p < 0.001$ ).

Table 4A.9 reports the duration of obesity (measured by BMI  $\geq 30$ ) by age and sex. The prevalence of men and women who were obese for three waves was highest among those aged 52–69 and gradually decreased in the oldest age groups. The prevalence of men who were obese for two waves was highest (14.7%) amongst the youngest age group, while for women it was highest for those aged 70–79 (19.8%). Around 62.8% of men aged 80+ and 57.1% of women aged 80+ were never obese.

The prevalence of central obesity did not show a clear pattern with age (Table 4A.10). Overall, men were more likely than women to have a high waist circumference on all three waves (29.5% of men and 17.1% of women,  $p < 0.001$ ), and this was also true in each age group. But in each age group, women were more likely than men to have a high waist circumference for two waves ( $p < 0.001$ ).

In both sexes, the prevalence of never being obese was greatest among those in the richest wealth quintile (Table 4A.11), and wealthy women were more likely than wealthy men never to be obese. In the poorest wealth quintile, 27.3% of women were obese on three waves, and this proportion fell linearly as wealth increased; but for men there was no clear wealth gradient in the prevalence of being obese on all three waves of measurement.

Overall, the prevalence of men and women who were never obese according to waist circumference was greatest in the richest wealth group (Table 4A.12). In both sexes, there was no clear relationship between wealth and the duration of central obesity.

### 4.5.3 Physical function, health and duration of obesity and central obesity by sex and wave

Among those aged 60 and over, the average walking speed decreased significantly over time in each of the duration-of-obesity categories, in both sexes (Figure 4.8). The average walking speed was higher among men and women who were never obese. Similar results were found for central obesity (Figure 4.9).

**Figure 4.8. Mean gait speed at each wave, by duration of obesity and sex**

Note: Obesity defined as BMI  $\geq 30$ . Age-standardised means. People aged 60 and over at wave 2.

**Figure 4.9. Mean gait speed at each wave, by duration of central obesity and sex**

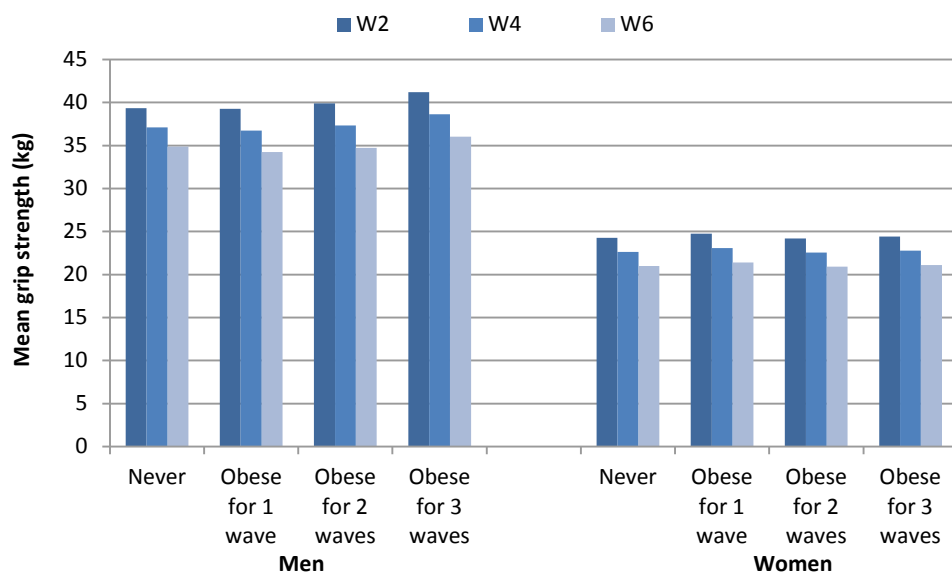

Note: Central obesity defined as waist circumference  $\geq 102$  cm for men and  $\geq 88$  cm for women. Age-standardised means. People aged 60 and over at wave 2.

Figure 4.10 shows the average hand grip strength at each wave by duration of obesity for men and women separately. Men who were obese on all three waves had greater hand grip strength at each wave than those who were obese on one wave or never. This result was not true among women, who at all time points and in all duration-of-obesity categories had lower hand grip strength than men.

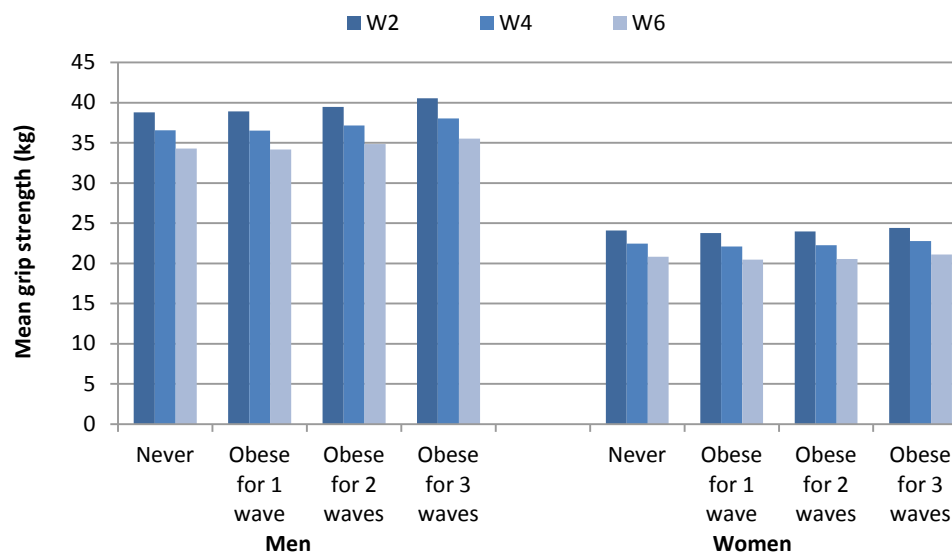

The average hand grip strength decreased significantly over time in all duration-of-central-obesity categories (Figure 4.11). For men, grip strength was highest among those who were obese on three waves. For women, the average hand grip strength did not vary according to the duration of central obesity.

**Figure 4.10. Mean hand grip strength at each wave, by duration of obesity and sex**

Note: Obesity defined as BMI  $\geq 30$ . Age-standardised means.

**Figure 4.11. Mean hand grip strength at each wave, by duration of central obesity and sex**

Note: Central obesity defined as waist circumference  $\geq 102$  cm for men and  $\geq 88$  cm for women. Age-standardised means.

Figure 4.12 shows the average glycated haemoglobin at each wave by duration of obesity in men and women. Over time, glycated haemoglobin increased significantly to a similar extent in each of the duration-of-obesity categories (5 mmol/ml); this was true in both sexes.

Similar results were found for central obesity (Figure 4.13). Women with sustained central obesity had lower levels of glycated haemoglobin than men in the same groups at each wave.

**Figure 4.12. Mean HbA1c at each wave, by duration of obesity and sex**

Note: Obesity defined as BMI  $\geq 30$ . Age-standardised means.

**Figure 4.13. Mean HbA1c at each wave, by duration of central obesity and sex**

Note: Central obesity defined as waist circumference  $\geq 102$  cm for men and  $\geq 88$  cm for women. Age-standardised means.

#### **4.5.4 Regression models for the association between changes in physical function and health and duration of obesity and central obesity**

The longitudinal analyses of this subsection use logistic regression models of wave 2 levels of physical function and health and changes over eight years on duration-of-obesity outcomes. The models were sequentially adjusted for age and sex (Model 1), cohabitation status, education and wealth (Model 2), CHD, diabetes and limiting long-standing illness (Model 3) and physical activity, alcohol consumption and smoking status (Model 4). The main outcomes – duration of obesity and central obesity – were recoded into binary variables indicating 0 ‘never obese or obese for one wave’ versus 1 ‘obese for two or three waves’.

Sequentially-adjusted regression models for wave 2 levels of gait speed and changes over eight years on the duration of obesity and central obesity are shown in Tables 4A.13 and 4A.14. Wave 2 gait speed and changes over time are grouped into tertiles to facilitate interpretation of results. Results show that compared with those with the fastest gait speed on wave 2, people aged 60 and over with intermediate gait speed levels (0.87 to 1.02 m/s) were 2.0 times ( $p<0.001$ ) more likely to have sustained obesity adjusted for age and sex; the odds ratio decreased to 1.7 after full adjustment but it remained statistically significant. Adjusting for age and sex, people with the slowest wave 2 walking speeds (0.29 to 0.86 m/s) were 4.1 times more likely to be persistently obese across waves than people with the fastest walking speed levels. The relationship remained statistically significant after full adjustment and the odds ratio only decreased by 25%. A steeper decline in walking speed over eight years was associated with increased odds (1.4,  $p<0.01$ ) of sustained obesity, compared with those who did not change walking speed or improved their speed; this relationship was approximately the same after full adjustment.

Similar results were found for central obesity (Table 4A.14) although the magnitude of the relationships between walking speed and duration of obesity is less strong than with obesity measured by BMI.

Tables 4A.15 and 4A.16 report the odds ratios for the relationship between changes in hand grip strength with obesity and central obesity respectively. The results show that people with an intermediate hand grip strength on wave 2 (26.0 to 35.9 kg) were less likely to be persistently obese (OR=0.7,  $p<0.01$ ) than people with highest levels of hand grip strength, while there was no significant relationship between low levels of hand grip strength and duration of obesity. Participants with the fastest declines in hand grip strength (–16.2 to –4.6 kg) were more likely to be obese on two or three waves than those who experienced small changes or an improvement in hand grip strength over eight years.

Interestingly, low hand grip strength at wave 2 was not associated with decreased odds of sustained central obesity. There was no significant relationship between changes in hand grip strength and duration of obesity (Table 4A.16).

The relationships between changes in glycated haemoglobin and duration of obesity and central obesity are shown in Table 4A.17 and 4A.18 respectively.

Older people with HbA1c concentrations of at least 58 mmol/mol at wave 2 were more likely to be persistently obese and centrally obese across waves than those with normal HbA1c levels, independently of all adjustment variables. Moderately large increases in HbA1c (of at least 4.1 mmol/mol over eight years) were also associated with higher odds of sustained obesity and central obesity.

#### **4.5.5 Conclusions**

In this section, we have reported the relationship between health and physical function and duration of obesity. We used glycated haemoglobin (HbA1c), walking speed and hand grip strength because they represent objective measures of health and physical function and they were available for the three waves considered in this chapter.

Slow walking speed in older adults is considered an early marker of disability and frailty, as well as a predictor of institutionalisation and mortality (Guralnik et al., 2000; Elbaz et al., 2013). Walking is a recommended form of exercise in obese people because it is beneficial for weight loss/management and health. However, obese people are more likely to walk slowly and less likely to engage in brisk walking, which can make it difficult to lose weight. In this section we have shown that intermediate levels of walking speed (0.87–1.02 m/s) and slow walking speed (below 0.87 m/s) were associated with increased likelihood of being obese (as measured by both BMI and waist circumference) over several waves. Moreover, those experiencing steep declines in walking speed were also more likely to be obese for longer.

Our results for the relationship between hand grip strength and duration of obesity showed that older people with low hand grip strength were less likely to have sustained obesity. This result is in line with previous studies showing that obese people usually have more muscle mass and more strength (Visser et al., 1998) than do non-obese people. However, we have shown that a steep decline in hand grip strength is associated with an increased risk of sustained obesity across waves. It is possible that the decline in hand grip strength is due to lack of physical exercise, which is more common among obese people. Although we have controlled for physical activity in our analyses, we have not controlled for changes in physical activity over time, which might have played a role in the observed decline over time in hand grip strength.

Diabetes is common among people with raised waist circumference and obese people. Glycated haemoglobin (HbA1c) is used to detect diabetes and it is known that HbA1c concentration steadily increases with age. Additionally, ageing is associated with several risk factors that contribute to elevated HbA1c, such as sedentary lifestyles, obesity and diabetes. In this section, we have shown that older people with poor blood glucose control ( $\geq 58$  mmol/mol) were more likely to show sustained obesity across waves and to have larger waist circumferences over time than people without diabetes or in control (HbA1c  $\leq 47.9$  mmol/mol). Increased levels of HbA1c were also associated with increased risk of duration of obesity and central obesity, independently of lifestyle factors, diabetes and other adjustment variables.

## 4.6 Obesity and physical activity

The final section of this chapter addresses the question of whether physical activity is related to obesity. The recommended level of physical activity for adults, including those 65 years or older, is at least 150 minutes of moderate activity in bouts of 10 minutes or more per week (Department of Health, 2011). Regular physical activity is key for maintaining good physical and mental health in older age (King and Guralnik, 2010), as corroborated by recent analyses of ELSA (Hamer et al., 2014). However, despite the common belief that physical inactivity is a major contributor to the obesity burden worldwide, the evidence supporting this link is mixed (Summerbell et al., 2009). In the absence of a calorie-restricted diet, physical activity alone is unlikely to lead to weight loss but it may help to maintain a more healthy weight. For example, in the Whitehall II study, men and women who adhered to the recommended physical activity guidelines (i.e. at least 2.5 hours of moderate physical activity per week) over a 10-year period had significantly lower levels of obesity, as measured by BMI and waist circumference, when compared with those who rarely adhered to these guidelines (Hamer et al., 2014).

A serious issue in physical activity research is that activity is notoriously difficult to measure. While self-report measures are relatively brief and inexpensive, and are therefore frequently used in large studies such as ELSA, they are prone to biases. This may be particularly true in older populations, where problems of recall arise, and where activity accumulates through everyday activities rather than formal exercise (Steptoe and Wikman, 2010). When compared with objective physical activity indicators, people's reports of their activity levels are imprecise and often overestimated, and the average correlation between self-reported and objective physical activity measures is about 0.37 (Prince et al., 2008). In previous waves of ELSA, physical activity was measured solely by self-report, but at wave 6 we measured objective physical activity in a subset of participants. The aim of the analyses described here is to explore whether self-reported and objective physical activity levels in ELSA respondents differ by obesity status, and whether the associations with obesity are comparable across these two different activity measures.

### 4.6.1 Methods

The analyses described in this section are based on a subsample of 244 respondents (127 men and 117 women) aged 67.5 on average (age range 55 to 81 years) who, in addition to having measures collected as part of wave 6 of ELSA, were requested to provide objective physical activity and sleep information (not detailed here). These data were collected during wave 6 with the GENEActiv accelerometer (Activinsights Ltd, Cambridgeshire, UK), a wrist-worn motion sensor which is ergonomic, fully waterproof, lightweight and unobtrusive. The major advantage of using the GENEActiv instead of an actigraph (the most widely-used objective physical activity measure) is its ability to measure water-based activities, such as swimming or aqua aerobics. In addition, the device provides raw data rather than just activity counts, which allows a greater sensitivity in determining the difference between sedentary and active behaviours. This is important given the emerging evidence linking

sedentary behaviour with adverse health outcomes including type 2 diabetes, cardiovascular disease and all-cause mortality (Grontved and Hu, 2011).

ELSA respondents were required to wear the GENEActiv continuously over seven days and nights as well as to complete a short sleep diary each day providing information about bed and wake-up times. The accelerometer was fitted at the end of the nurse visit in participants' homes. They were instructed to wear the device on the dominant wrist. Activity was sampled at 87.5 Hz and stored in gravity units (1 unit = 9.81 m/s<sup>2</sup>). For the purpose of the analyses described graphically (Figures 4.14–4.16), activity counts were aggregated over each minute and were categorised based on the manufacturer's cut-off points into sedentary (<241 activity counts), light ( $\geq$ 241 and <339 activity counts) and moderate/vigorous ( $\geq$ 339 activity counts) activity levels. So for each participant for every hour of every 24-hour period, we had data on sedentary, light and moderate/vigorous activity. Results were averaged into weekday and weekend day means, but here only the weekday results are presented. The average number of days contributing to the weekday means was 4.0 (range 0 to 5). For cross-tabulations and logistic regression analyses, activity counts from 7:00am until 10:00pm on weekdays were summed and then divided into tertiles. The lowest tertile corresponds to the lowest activity levels. The categorisation of activity data in these analyses was designed to assess relative differences in activity levels between obese and non-obese respondents, so it does not correspond to the current physical activity guidelines.

Self-reported physical activity was assessed by asking participants how often they engaged in vigorous or moderate physical activity; the response options were 'hardly ever or never', 'one to three times a month', 'once a week' and 'more than once a week'. The items were modified from the Whitehall II Health Questionnaire administered in 1991–93 (Marmot et al., 1991).

In this section, responses to *both* types of activity were combined to create 'sedentary', 'light' and 'moderate/vigorous' activity categories. Specifically, respondents were classified into the 'sedentary' category if they reported engaging hardly ever or never in vigorous activity and less than once a week in moderate activity. Respondents reporting engaging hardly ever or never, or one to three times a month, in vigorous activity and more than once a week in moderate activity were classified as engaging in 'light' physical activity. Lastly, those engaging in vigorous/moderate activity one to three times a month, once a week, or more than once a week were classified into the 'moderate/vigorous' activity category.

#### **4.6.2 Objective and self-reported physical activity and obesity**

There were 78 obese (32.0%) and 166 non-obese (68.0%) participants in this subset of ELSA wave 6 respondents. Figure 4.14 shows that on weekdays, both obese and non-obese ELSA respondents spent on average between 40 and 50 minutes of each waking hour being sedentary. But obese participants spent less time in light or moderate/vigorous activity than their non-obese counterparts ( $p < 0.001$ ).

**Figure 4.14. Mean minutes per hour<sup>a</sup> of sedentary, light and moderate/vigorous physical activity during waking hours (7am–10pm) of weekdays**

<sup>a</sup> Adjusted for age, sex and wealth.  
 Note: Obesity defined by BMI  $\geq 30$  kg/m<sup>2</sup>.

**Figure 4.15. Mean duration of sedentary, light and moderate/vigorous activity per hour across all 24 hours of the day (averaged over weekdays): obese ELSA respondents**

Figures 4.15 and 4.16 illustrate the profile over the entire 24-hour period, averaged over weekdays, and further demonstrate that during waking hours both obese (Figure 4.15) and non-obese (Figure 4.16) participants spent most of their time in sedentary activities. However, obese respondents spent less time doing light and moderate/vigorous activities. For example, it can be seen

**Figure 4.16. Mean duration of sedentary, light and moderate/vigorous activity per hour across all 24 hours of the day (averaged over weekdays): non-obese ELSA respondents**

that obese respondents spent an average of 20 minutes or more per hour in light and moderate/vigorous activities only for the period 11:00am–11:59am. By contrast, people who were not obese spent all the hours between 9:00am and 5:00pm being active for at least 20 minutes in each hour.

Table 4A.19 depicts mean obesity levels in the ELSA subsample who carried out objective physical activity monitoring. As in the full sample, both men and women were overweight on average. According to central obesity criteria defined by waist circumference, women were on average obese, with men right on the obesity threshold. In analyses carried out separately for respondents younger than 70 years and those aged 70 or older, BMI was lower in the older group for both sexes, and the same finding was obtained for central obesity, particularly in women (data not shown).

Table 4A.20 shows obesity levels by wealth. Obesity defined by BMI was most common in the lowest (poorest) and third wealth quintiles, while central obesity indexed by waist circumference was highest in the lowest three wealth quintiles. Central obesity levels were markedly higher across all wealth categories than obesity levels assessed by BMI, though the criteria are not strictly comparable.

Table 4A.21 displays the prevalence of obesity by self-reported and objective physical activity. In terms of physical activity defined by self-report, nearly 43% of respondents who were sedentary were also obese, as defined by BMI, but the prevalence rose to nearly 65% for central obesity (measured by waist circumference). The rates of obesity were halved among participants reporting moderate or vigorous physical activity. For example, only 20.6% of individuals in the moderate/vigorous activity category were obese, as defined by BMI.

Similarly to self-reported data, when activity was measured objectively a greater proportion of sedentary respondents were classified as obese.

However, while the proportion of obese respondents as defined by BMI decreased in a linear fashion from sedentary to moderate/vigorous activity (50.0%, 31.2% and 17.3%, respectively), central obesity prevalence varied markedly less. For example, 51.9% of sedentary respondents were classified as centrally obese, but the prevalence of central obesity was only slightly lower in those who engaged in moderate/vigorous physical activity (48.8%).

Table 4A.22 depicts results of logistic regression models when obesity was regressed on physical activity. In terms of self-reported activity, it can be seen that in comparison with respondents reporting moderate/vigorous activity, those reporting light and sedentary activity both had a significantly increased odds ratio (OR) of obesity (OR=2.14,  $p=0.037$  and OR=2.79,  $p=0.004$ , respectively, for Model 1). In Model 2, after adjustment for socio-economic circumstances, only respondents reporting sedentary activity were significantly more likely to be obese (OR=2.58,  $p=0.008$ ), while those in the light activity category were not (OR=2.04,  $p=0.052$ ). Model 3 further adjusted for medical conditions, and showed that neither light nor sedentary activity remained associated with obesity. Unsurprisingly, light and sedentary activity remained non-significant predictors of obesity after additional adjustment for smoking and alcohol consumption.

In the analyses relating objective physical activity with obesity, the associations were much stronger and survived adjustment for covariates (lower half of Table 4A.22). In Model 1, after adjustment for age and sex, respondents engaging in light activity were over twice as likely to be obese (OR=2.37,  $p=0.033$ ), while sedentary people had an even larger risk of being obese (OR=5.96,  $p<0.001$ ), when compared with those who did moderate/vigorous activities. Further adjustment for wealth, education and cohabitation status in Model 2 attenuated these results only slightly, and both light and sedentary activity remained strong predictors of obesity after medical conditions were added into the analysis in Model 3. The association with obesity became slightly stronger in Model 4 (light activity: OR=2.80,  $p=0.021$ ; sedentary activity: OR=6.03,  $p<0.001$ ), when health behaviours were added into the analysis.

Table 4A.23 shows the regressions on central obesity. Compared with self-reported moderate/vigorous activity, respondents reporting light (OR=1.99,  $p=0.039$ ) and sedentary activity (OR=2.96,  $p=0.001$ ) were significantly more likely to be obese after adjustment for sex and age (Model 1). After further adjustment for covariates, only sedentary activity remained a predictor of central obesity (Models 2–4). The corresponding logistic regressions relating objective activity with central obesity showed that the light activity category was not related to risk of obesity in any of the four models. However, the associations between central obesity and sedentary activity were much stronger than those for self-reported activity. In Model 1, sedentary activity was a significant predictor of central obesity (OR=4.50,  $p<0.001$ ), and this association was only slightly attenuated after socio-economic factors were added in Model 2. Sedentary activity remained significantly associated with obesity after further adjustment for medical conditions (Model 3), when compared with the moderate/vigorous category. Finally, when smoking and alcohol consumption entered the analysis in Model 4, the association was still highly significant and largely unchanged (OR=3.61,  $p=0.001$ ).

### **4.6.3 Conclusions**

In the ELSA subsample described here, men and women were generally overweight, with 31.5% being obese, and women were more likely than men to have waist circumferences above threshold. This is in line with the literature suggesting that central adiposity is more prevalent in women, in particular those post-menopause and/or older (Donato et al., 2006; Health and Social Care Information Centre, 2014). As with the full sample, obesity was more prevalent among those with less wealth.

Both self-reported and objective activity measures indicated that levels of sedentary behaviour were high, particularly among those who were obese. Because these data are cross-sectional, it is uncertain whether sedentary behaviour contributed to obesity. It has been suggested, however, that a sedentary lifestyle to some extent may result from obesity since physical activity is associated with greater physical effort among those carrying an excess weight (Ekelund et al., 2008; Golubic et al., 2013; Hamer et al., 2014). It is also notable that, according to the objective activity measure, non-obese participants spent considerably more time engaging in light and moderate/vigorous activity than did the obese. In fact, the amount of moderate/vigorous activity shown in Figure 4.16 suggests that non-obese ELSA respondents were close to meeting the recommended level of 150 minutes of physical activity per week. However, it should be borne in mind that we were not assessing prolonged bouts of moderate/vigorous activity, and brief episodes of intensive activity lasting only a minute, such as walking fast from one room to the other, contributed to these values, which accumulated over the recording period.

After adjustment for potentially confounding variables, light and sedentary self-reported activity were not associated with obesity indexed by BMI, while both objective light and sedentary activity remained strongly linked to obesity in the fully-adjusted models. This suggests that the objective activity assessments were much more sensitive to adiposity than were self-report measures. BMI is a measure of overall obesity while waist circumference is a measure of central adiposity, and the literature suggests that the latter is more strongly associated with physical exercise (Lee et al., 2005; van der Heijden et al., 2010). Results for obesity assessed by waist circumference were more comparable across the measures of activity, since for both self-reported and objective indices light activity was unrelated to obesity, but the sedentary category remained a strong predictor in fully-adjusted models. These findings are, of course, cross-sectional, so no conclusions about the direction of effects can be drawn.

## 5. Methodology

**Sally Bridges** *NatCen Social Research*

**David Hussey** *NatCen Social Research*

**Margaret Blake** *NatCen Social Research*

**Dan Philo** *NatCen Social Research*

This chapter presents a summary of the survey methodology for the sixth wave (2012–13) of the English Longitudinal Study of Ageing. It includes a brief account of the sample design (Section 5.1), the content of the interview (Sections 5.2–5.4) and the approach to fieldwork (Section 5.5). It also provides basic information about survey response rates (Section 5.6) and the weighting strategies used in this report (Section 5.7). Section 5.8 concludes. Further detail is provided in the ELSA technical reports, which can be accessed via the ELSA website (<http://www.elsa-project.ac.uk>).

A summary of the key points relating to wave 6 is given below:

- The wave 6 (2012–13) core questionnaire was similar to that used in the previous waves. Some content was rotated back on and some off the questionnaire, but the structure and the majority of content were the same.
- As in previous waves, participants who completed the main ELSA interview were asked to complete a self-completion questionnaire. The content was broadly the same as in previous waves.
- In addition to the core self-completion, participants were asked to complete a self-completion about sexual experience, attitudes and desire.
- A nurse visit was offered to all core members who took part in an interview in person at wave 6. The nurse visit was broadly similar to the visits at wave 2 and wave 4. New spirometers were used to measure lung function and a hair sample was taken to measure cortisol, in place of the saliva sample taken at previous waves.
- Four cohorts of people made up the ELSA sample issued at wave 6:
  - **Cohort 1**<sup>1</sup> born on or before 29 February 1952. Selected from Health Survey for England (HSE) 1998, 1999 and 2001. First interviewed at ELSA wave 1 (2002–03) aged 50 and over. Cohort 1 core members and their partners represented 54.1% of all issued cases at wave 6.
  - **Cohort 3** born between 1 March 1952 and 1 March 1956. Selected from four years of HSE (2001 to 2004). First interviewed at ELSA wave 3 (2006–07). Cohort 3 core members and their partners represented 11.2% of all issued cases at wave 6.

---

<sup>1</sup> All longitudinal analysis in this report is based on Cohort 1 core members interviewed at every wave of ELSA.

**Cohort 4** born between 1 March 1933 and 28 February 1958. Selected from HSE 2006. Sampled for ELSA wave 4 (2008–09) aged 50–74. Cohort 4 core members and their partners represented 18.4% of all issued cases at wave 6.

**Cohort 6** born between 1 March 1956 and 28 February 1962. Selected from HSE 2009, 2010 and the first half of 2011. Wave 6 (2012–13) was their first opportunity to be interviewed at ELSA as a refresher sample aged 50–55 at the time of sampling. Cohort 6 core members and their partners represented 16.2% of all issued cases at wave 6.

- A total of 10,601 main interviews were completed at wave 6 across all four cohorts. Much of the analysis in this chapter focuses on core members. Core members are defined as age-eligible sample members who participated the first time they were approached to join the ELSA study. They represent the core element of the continuing ELSA sample. At wave 6, 5,659 interviews were with Cohort 1 core members from the original wave 1 sample, 888 were with core members from Cohort 3, 1,796 were with core members from Cohort 4 and 826 were with core members from Cohort 6. The remaining interviews were with partners of core members (defined as either core, young, old or new partners – see Box 5.1 later).

## 5.1 Sample design

The ELSA sample is selected to be representative of people aged 50 years and over, living in private households in England. It was drawn from households who had previously responded to the Health Survey for England so that the study could benefit from data that had already been collected. Some background information about the HSE is provided below.

### Health Survey for England

The HSE is an annual cross-sectional household survey that gathers a wide range of health data and biometric measures. Each of the main HSE samples had originally been drawn in two stages. First, postcode sectors were selected from the Postcode Address File, stratified by health authority and the proportion of households in the non-manual socio-economic groups. Addresses were then selected systematically from each sector and 10 adults and 2 children in each household were deemed eligible for interview.

Eligible individuals at HSE were asked to participate in a personal interview for ELSA, followed by a nurse visit. Further details about the HSE years used to select the ELSA sample are available from the HSE Methodology Reports (Erens and Primatesta, 1999; Erens et al., 2001; Prior et al., 2003; Sproston and Primatesta, 2003; Sproston and Primatesta, 2004; Sproston and Mindell, 2006; Craig and Mindell, 2008; Craig and Hirani, 2010; Craig and Mindell, 2011; Craig and Mindell, 2012).

### ELSA Cohort 1

The original cohort at wave 1 (persons born on or before 29 February 1952) were selected from households who had previously responded to the HSE in 1998, 1999 and 2001. The ELSA wave 1 interview took place in 2002–03,

providing the baseline for the study. Overall, there were 12,099 achieved interviews at wave 1 and, of these, 11,391 became Cohort 1 core members. Interviews with Cohort 1 core members and their partners were attempted every two years following wave 1 (wave 2 in 2004–05, wave 3 in 2006–07, wave 4 in 2008–09, wave 5 in 2010–11 and wave 6 in 2012–13).

### **ELSA Cohort 3**

At wave 3, a ‘refresher’ cohort of people just entering their 50s (born between 1 March 1952 and 1 March 1956) was introduced (Cohort 3). The sample used to form Cohort 3 was selected from four survey years of the HSE (2001 to 2004). There were 1,733 Cohort 3 interviews at wave 3 and, of these, 1,276 became core members. The majority of Cohort 3 core members (87%) came from HSE households issued for the first time at ELSA wave 3; the remainder were mainly younger partners in Cohort 1 households who were reclassified as Cohort 3 core members because they now met the age criteria. There are now four waves of interviews with Cohort 3 core members and their partners (wave 3 in 2006–07, wave 4 in 2008–09, wave 5 in 2010–11 and wave 6 in 2012–13).

### **ELSA Cohort 4**

A cohort of people born between 1 March 1933 and 28 February 1958 (aged 50–74 at time of sampling) was added to the wave 1 and wave 3 cohorts in 2008–09 (henceforth referred to as Cohort 4). The main wave 4 cohort was selected from HSE 2006. There were 2,590 interviews at wave 4 and, of these, 2,290 became Cohort 4 core members. The group of Cohort 4 core members includes 248 people who were mistakenly not issued at wave 3 (as part of Cohort 3) and were followed up for interview at wave 4 instead. Wave 6 represents the third wave of interviews with Cohort 4 members and their partners (wave 4 in 2008–09, wave 5 in 2010–11 and wave 6 in 2012–13).

### **ELSA Cohort 6**

At wave 6, a further ‘refresher’ cohort of people born between 1 March 1956 and 28 February 1962 (aged 50–55) was added in 2012–13 (Cohort 6). Cohort 6 was selected from participating individuals in HSE 2009, 2010 and the first half of 2011. There were 1,154 Cohort 6 interviews at wave 6 and, of these, 826 became core members. Wave 6 (2012–13) is the first wave of interviews with Cohort 6 members.

### **Types of eligible sample members**

Box 5.1 summarises the different types of sample members eligible for the ELSA study – namely, core members, core partners, younger partners, older partners and new partners.

### Box 5.1. ELSA sample members

**Core members** are individuals who had been living within the household that participated in HSE (although not all were personally interviewed for HSE). They met the age criteria for the ELSA study at the time of their first ELSA interview and had their first ELSA interview at a private residential address in England.

**Core partners** are individuals who, like core members, had been living within the household at the time of the HSE interview and were age-eligible for inclusion in ELSA. However, they were *not* interviewed the first time they were approached to join ELSA, so missed the baseline survey. As a consequence, they are now only approached by virtue of being the partner of a core member. (In Cohort 6, core partners are those who are age-eligible but did not take part in HSE themselves but did take part in ELSA wave 6 as a partner.)

**Younger partners** are the cohabiting younger spouses or partners of core members, who were living within the household at the time of HSE and the first ELSA interview, but who did not meet the age criteria to be classified as a core member.

**Older partners (for Cohort 3, 4 and 6 only)** are the older cohabiting spouses or partners of age-eligible sample members selected for ELSA, who had been living within the household at the time of the HSE or ELSA interview.

**New partners** are the cohabiting spouses or partners (of any age) of core members at the time of the ELSA interview who have joined the household *since* the original HSE interview.

**Sample members** are neither core members nor partners. These people were originally sampled for ELSA in their own right as they took part in HSE and were age-eligible for ELSA; however, they did not take part in the first ELSA wave they were invited to take part in and so could not become core members. They are retained in the sample file and have an opportunity to take part in future waves because they live with a core member of the sample but they are not cohabiting partners, e.g. they may be siblings, children or parents of a core member.

### Eligibility criteria for wave 6 main interview

The eligibility criteria for a wave 6 interview are given below:

- Individuals were not eligible for follow-up if they had since died, asked not to be revisited or moved out of Britain.<sup>2</sup> For the refresher sample (Cohort 6), individuals are not eligible if they have moved out of England.
- Core members who later moved into a care home or institution, or into Scotland or Wales, after their first ELSA interview (baseline wave) remain eligible for all future ELSA interviews. A total of 72 productive institutional interviews were conducted at wave 6. These are excluded from some response rates presented in Section 5.6 because, for some analyses, they no longer represent the population of interest.
- An interview was attempted with all partners who had been living with a core member at the time of an ELSA interview in either wave 4 or wave 5 and had been separated, divorced or widowed from them, so that we could understand their circumstances after this event had occurred.
- Partners who stopped living with their core member partner are only eligible to be interviewed once following the split. Therefore if ex-partners

<sup>2</sup> Note that sample members are followed if they move to Scotland or Wales but not if they move to Northern Ireland.

were interviewed at wave 5 (or before), they were not re-contacted at wave 6. In the refresher sample, partners who had split from their core member partner were not eligible for an interview.

## **5.2 Development of the wave 6 interview (2012–13)**

Extensive discussion took place with ELSA collaborators about what changes were needed for the wave 6 interview and what new topics to include. There was a pilot in June 2011 to test the content that was new to ELSA. This included the sexual activity self-completion, new questions about receipt and provision of social care, and a new test of fluid intelligence in the cognitive function section. This pilot included an element of cognitive interviewing for some respondents, to understand the process by which they understood and responded to the new questions. It was also important to assess the acceptability of these new questions to ELSA respondents. There was a dress rehearsal from November 2011 to January 2012 to test the overall survey process including main interview and nurse fieldwork. From this, the research team collected feedback on the overall survey content and procedures to be implemented at wave 6, and developed a plan for interviewer and nurse training.

## **5.3 Structure and content of the wave 6 interview (2012–13)**

As at previous waves, the wave 6 main survey comprised a personal face-to-face interview and a self-completion questionnaire.

The structure of the main interview was the same as it had been at previous waves. In brief:

- In households with one respondent, or where two respondents were interviewed separately, each interview followed the course set out in Box 5.2, though some flexibility was given in the order of the walking-speed, income and assets, and housing modules.
- In households where more than one eligible respondent agreed to take part, two individuals could be interviewed in a single session (unless they kept their finances separately and were not prepared to share this information). In these ‘concurrent’ sessions, the two respondents were interviewed alongside each other, but were separated during the course of the interview so that the later modules assessing cognitive function and collecting information about expectations for the future, psychosocial health, demographic information and consents for linkages to administrative data could be administered in private.
- In addition to the core self-completion questionnaire, a self-completion questionnaire was introduced at wave 6 asking about sexual experience, attitudes and desire.

**Box 5.2. Content of the ELSA interview at wave 6 (2012–13)**

**Household demographics:** collected or updated demographic information about everyone living in the household, including sex, age and relationships to each other, and collected or updated information about children living outside the household.

**Individual demographics:** collected or updated details about respondents' legal marital status, parents' age and cause of death, and number of living children.

**Health:** collected or updated self-reported general health, long-standing illness or disability, eyesight, hearing, specific diagnoses and symptoms, pain, difficulties with daily activities, smoking, mental health, urinary incontinence, falls and fractures, quality of care and cancer screening. New health questions at wave 6 included those on bowel incontinence. Questions on sleep and balance were included again at wave 6. Questions about dental health were omitted from wave 6.

**Social care:** new questions about receipt of social care were added at wave 6 to follow on from existing questions about ADLs and IADLs. These replaced previous questions about care received. Topics included the nature of care received, who it was received from, the amount received and payments made for care.

**Social participation:** covered the use of public transport.

**Work and pensions:** collected or updated current work activities, current and past pensions, reasons for job change, health-related job limitations and working beyond the state pension age and state pension deferral. At wave 6, questions about knowledge of the male state pension age were included.

**Income and assets:** assessed the income that respondents received from a variety of sources over the last 12 months: wages, state pensions, private pensions, other annuity income and state benefits; also collected financial and non-financial assets. Questions about perceived financial position relative to others were omitted from wave 6. Questions about lifetime receipt of gifts and inheritances were included in wave 6.

**Housing:** collected or updated current housing situation (including size and quality), housing-related expenses, adaptations to accommodation for those with physical impairments, ownership of durable goods and cars, and consumption including food in and out of home, fuel, durables and clothing.

**Cognitive function:** measured different aspects of the respondent's cognitive function, including memory, speed and mental flexibility.

**Expectations:** measured expectations for the future in a number of dimensions, financial decision-making and relative deprivation. Questions about movement into a nursing home and future housing and care needs were added at wave 6.

**Effort and reward:** assessed the relationship between effort and reward in relation to voluntary and caring activities. New questions on care provided to others were integrated into existing questions in this section.

**Psychosocial health:** measured how the respondent viewed his or her life across a variety of dimensions.

**Walking speed:** for respondents aged 60 and over, a 'timed walk' with the respondent walking a distance of 8 feet (244 cm) at their usual walking pace.

**Final questions:** collected any missing demographic information and updated contact details and consents.

**Self-completion questionnaires:** covered quality of life, social participation, altruism, control at work, life satisfaction, consumption of fruit and vegetables, social networks and alcohol consumption. There was also a new self-completion questionnaire introduced at wave 6 about sexual experience, attitudes and desire.

- Because wave 6 included two self-completion questionnaires, the procedures differed slightly from previous waves. In existing sample households (which had taken part in at least one wave of ELSA), the main self-completion was provided in advance of the interview (in person by the interviewer or by post). Respondents could complete it before their interview. In refresher sample households, the main self-completion was never given in advance and was usually completed after the face-to-face interview. During concurrent interviews, the sexual experience questionnaire was completed while the other person in the concurrent interview session completed the ‘private’ modules described above. If the eligible individual was interviewed alone, the sexual experience self-completion questionnaire was normally completed after the face-to-face interview was over and the interviewer had left the household. Completed questionnaires were returned by the interviewer (if they had been completed before or during the interview), posted back by the respondent or collected by the nurse during the subsequent nurse interview.
- Where two or more eligible individuals lived in a household, one was nominated as the respondent for the housing module. Similarly, one individual was asked to be the respondent to report on income and assets on behalf of each benefit unit. However, if two individuals in the same benefit unit kept their finances separately, the data for each financial unit were collected separately.

Overall, the intention at wave 6 was to collect data about the same topics as at the previous waves, but some changes to the questionnaire were made. The new topics introduced at wave 6 are included in Box 5.2, as well as key questions chosen to be omitted for this wave (for example, due to wave rotation).

The interview ended with a request to confirm or amend consent to obtain health data (Hospital Episode Statistics) and economic data (benefits and National Insurance information) from administrative sources. Consent for NHS Central Register linkage was requested from the refresher sample only if consent had not been provided at HSE. None of these consents was collected from individuals for whom a proxy respondent was needed. Contact details were requested for a stable address and for a nominated individual who might respond if a proxy, institutional or end-of-life interview were needed in the future.

## **5.4 Wave 6 nurse interview**

### **Eligibility criteria for wave 6 nurse interview**

After carrying out the interview, the interviewer made an appointment for the nurse to visit eligible respondents or set up contact between the nurse and respondent. The eligibility criteria for a wave 6 nurse interview are given below:

- Core members who completed a main interview in person at wave 6 were eligible for a nurse visit.

- Partners were not eligible for nurse visits but were given a nurse visit if they requested it and it would assist with their future participation in the survey.
- Individuals who completed an interview by proxy were not eligible for a nurse visit.
- There were specific eligibility criteria for each measure conducted by the nurse. These are outlined briefly below and in more detail in the Nurse User Guide (available from the UK Data Service).

### Structure and content of the wave 6 nurse interview (2012–13)

The nurse visited the respondent to carry out a series of measurements listed in Box 5.3. These were only obtained if the appropriate consents were given and the respondent was able to respond to relevant safety and eligibility questions.

As described in Box 5.3, a blood sample was collected from respondents who gave consent for this in order to examine the factors outlined in Box 5.4.

#### Box 5.3. Content of the ELSA nurse interview at wave 6 (2012–13)

The nurse visit included several standard measures including:

**Blood pressure**

**Lung function:** a measure of how much air respondents can blow out from lungs, measured using a spirometer.<sup>a</sup>

**Blood sample:** most respondents under the age of 80 were asked to fast before giving the sample. The uses to which the sample was put are listed in Box 5.4.

**Hair sample:** respondents were asked to give a small sample of hair to measure cortisol, which is an indicator of stress.<sup>b</sup>

**Anthropometric measures:** weight, standing height and waist measurement (to assess the distribution of body fat across the body).

In addition, nurses took four **physical performance** measures. Taken together with the gait speed (or timed walk) measure carried out during the personal interview, these provide an excellent way of tracking change in physical well-being over time:

**Grip strength:** a measure of upper body strength, during which the respondent was asked to squeeze a grip gauge up to three times with each hand.

**Chair rises:** a measure of lower body strength, during which respondents were asked to stand up from a firm chair without using their arms. If they succeeded, they were asked to stand up and down as quickly as they can for either five rises if they are aged 70 years and over or up to ten rises if aged 69 years and under.

**Balance:** respondents were asked to stand in three different positions for up to 30 seconds.

**Leg raise:** respondents under 70 years old were asked to lift one foot off the ground for up to 30 seconds.

Questions about **prescribed medication** were introduced at wave 6, collecting the details of up to 40 prescribed medications currently being taken.

<sup>a</sup> Due to advancements in technology, new spirometers (NDD Easy On-PC) were used to measure lung function in wave 6. These new spirometers assess whether the measurement was technically acceptable and instruct nurses when another measurement is needed. As a result of the new equipment and improved nurse training on measuring lung function, lung function data from wave 6 should not be compared directly with data from wave 4.

<sup>b</sup> In previous waves with a nurse visit, cortisol was measured using a saliva sample collected over a 24-hour period.

#### Box 5.4. Purpose of the blood measurements at wave 6 (2012–13)

**Factors increasing heart disease risk:** fibrinogen, total cholesterol, high triglycerides, high C-reactive protein (also a marker for inflammation) and low-density lipoprotein.

**Risk of diabetes:** fasting glucose and glycated haemoglobin.

**Protective factors against heart disease:** high-density lipoprotein and apolipoprotein E.

**Checks on iron levels and anaemia:** ferritin, haemoglobin, white blood cell count and mean corpuscular haemoglobin.

**Other health:** vitamin D for bone health and IGF-1 for digestion, immune system etc.

**Genetics:** genetic factors are associated with some common diseases, such as diabetes and heart disease, and relate to general biological aspects of the ageing process.

## 5.5 Fieldwork

Each eligible individual was sent an advance letter inviting them to take part at wave 6. Interviewers then contacted the household by phone or in person to arrange an appointment for the face-to-face interview. A number of approaches were used to encourage participation among the sample, many of which were similar to those described in the first ELSA report (Marmot et al., 2003). Fieldwork for the sixth wave of ELSA began in May 2012 and spanned 13 months, finishing in June 2013.

## 5.6 Survey response

In this section, we present summary information about survey response in wave 6 (2012–13) for the main interview and nurse interview.

### Response to main interview

Survey response and quality of fieldwork were carefully monitored throughout the study period. Ultimately, the ELSA wave 6 fieldwork produced 10,601 productive interviews (including both proxy and partial interviews). Of these interviews, 72 were conducted with individuals who had originally been interviewed in a private household and had since moved into an institution and were therefore still eligible for follow-up (see Section 5.1).

Table 5.1 shows the number of interviews conducted for Cohort 1 broken down by sample type. A total of 6,171 interviews were achieved with members of Cohort 1 at wave 6, and 5,659 of these were with core members.

Table 5.2 presents the pattern of response over time for the 5,659 Cohort 1 core members who were interviewed at wave 6 and gives a breakdown of the type of wave 6 interview conducted with them. Eighty-four per cent of Cohort 1 core members interviewed at wave 6 had completed an interview at every wave since wave 1. Ninety-five per cent of Cohort 1 core members interviewed at wave 6 were interviewed in person.

Table 5.3 gives a breakdown of the number of achieved interviews by each sample type for Cohort 3. A total of 1,225 interviews were conducted overall and 888 of these were with core members.

**Table 5.1. Respondents, by sample type: Cohort 1**  
*Respondents in 2012–13, including proxies*

	<b>Number of respondents</b>
Core member <sup>a</sup>	5,659
Core partner <sup>b</sup>	124
Younger partner	269
New partner	119
<i>Unweighted N</i>	<i>6,171</i>

<sup>a</sup> Born on or before 29 February 1952.

<sup>b</sup> Core partners are individuals sampled as core members in wave 1 but who did not respond in wave 1 and so were only interviewed in wave 6 by virtue of being the partner of a core member.

**Table 5.2. Core member respondents, by situation in wave 6 (2012–13): Cohort 1**  
*Core member respondents in 2012–13*

	<b>Number of respondents</b>	<b>%</b>
<b>Pattern of response</b>		
All six waves	4,766	84
Missed one or more waves	893	16
<b>Type of interview</b>		
Full interview in person	5,351	95
Full interview by proxy	215	4
Partial interview in person	23	<1
Partial interview by proxy	1	<1
Institutional interview in person	11	<1
Institutional interview by proxy	58	1
<i>Unweighted N</i>	<i>5,659</i>	<i>100</i>

Note: Columns may not add up to 100% because of rounding.

**Table 5.3. Respondents, by sample type: Cohort 3**  
*Respondents in 2012–13, including proxies*

	<b>Number of respondents</b>
Core member <sup>a</sup>	888
Core partner <sup>b</sup>	15
Younger partner	193
Older partner	93
New partner	36
<i>Unweighted N</i>	<i>1,225</i>

<sup>a</sup> Born between 1 March 1952 and 1 March 1956.

<sup>b</sup> Core partners are individuals sampled as core members in wave 3 but who did not respond in wave 3 and so were only interviewed in wave 6 by virtue of being the partner of a core member.

Table 5.4 shows the pattern of response over time for the 888 Cohort 3 core members interviewed at wave 6 and the type of interview conducted at wave 6. Eighty-eight per cent of Cohort 3 core members interviewed at wave 6 also took part at the three preceding waves for which they were eligible (waves 3, 4 and 5). Ninety-five per cent of Cohort 3 core members interviewed at wave 6 were interviewed in person.

Table 5.5 presents the breakdown of achieved interviews by sample type for Cohort 4. A total of 2,051 interviews were conducted and 1,796 of these were with core members.

Table 5.6 shows the type of wave 6 interview conducted with the 1,796 core members from Cohort 4. Ninety-six per cent of Cohort 4 core members interviewed at wave 6 also took part at the two preceding waves for which they were eligible (waves 4 and 5). Ninety-seven per cent of Cohort 4 core members interviewed at wave 6 were interviewed in person.

Table 5.7 presents the breakdown of achieved interviews by sample type for Cohort 6. A total of 1,154 interviews were conducted and 826 of these were with participants who then became core members.

**Table 5.4. Core member respondents, by situation in wave 6 (2012–13): Cohort 3**

*Core member respondents in 2012–13*

	Number of respondents	%
<b>Pattern of response</b>		
All four waves (waves 3, 4, 5 & 6)	781	88
Missed one or more waves	107	12

Full interview by proxy	32	4
Partial interview in person	10	1
Partial interview by proxy	0	0
Institutional interview in person	1	<1
Institutional interview by proxy	0	0
<i>Unweighted N</i>	888	100

Note: Columns may not add up to 100% because of rounding.

**Table 5.5. Respondents, by sample type: Cohort 4**

*Respondents in 2012–13, including proxies*

	Number of respondents
Core member <sup>a</sup>	1,796
Core partner <sup>b</sup>	26
Younger partner	91
Older partner	109
New partner	29
<i>Unweighted N</i>	2,051

<sup>a</sup> Born between 1 March 1933 and 28 February 1958.

<sup>b</sup> Core partners are individuals sampled as core members in wave 4 but who did not respond in wave 4 and so were only interviewed in wave 6 by virtue of being the partner of a core member.

Table 5.8 shows the type of wave 6 interview conducted with the 826 core members from Cohort 6. As wave 6 was the first wave of fieldwork for this cohort, no pattern of response is shown. Ninety-seven per cent of Cohort 6 core members interviewed at wave 6 were interviewed in person.

**Table 5.6. Core member respondents, by situation in wave 6 (2012–13): Cohort 4**

*Core member respondents in 2012–13*

	Number of respondents	%
<b>Pattern of response</b>		
All three waves (waves 4, 5 & 6)	1,722	96
Missed one or more waves	74	4
<b>Type of interview</b>		
Full interview in person	1,736	97
Full interview by proxy	53	3
Partial interview in person	5	<1
Partial interview by proxy	0	0
Institutional interview in person	0	0
Institutional interview by proxy	2	<1
<i>Unweighted N</i>	<i>1,796</i>	<i>100</i>

Note: Columns may not add up to 100% because of rounding.

**Table 5.7. Respondents, by sample type: Cohort 6**

*Respondents in 2012–13, including proxies*

	Number of respondents
Core member <sup>a</sup>	826
Core partner <sup>b</sup>	28
Younger partner	146
Older partner	144
New partner	10
<i>Unweighted N</i>	<i>1,154</i>

<sup>a</sup> Born between 1 March 1956 and 28 February 1962.

<sup>b</sup> In wave 6, only people who took part in HSE were classed as core members. Core partners in wave 6 are those who were age-eligible for ELSA but who were not classed as core members because they had not taken part in HSE.

**Table 5.8. Core member respondents, by situation in wave 6 (2012–13): Cohort 6**

Partial interview by proxy	0	0
<i>Unweighted N</i>	<i>826</i>	<i>100</i>

Note: Last column may not add up to 100% because of rounding.

## Response rates

There is no universally accepted definition of response rate. An important distinction exists between *field* and *study* response rates. Fieldwork response rates are based on the subset of individuals actually issued for interview at any particular wave. Study response rates for longitudinal surveys are broader in that they relate back to the originally selected sample, irrespective of whether eligible cases were issued to field at any particular wave.

Both field and study rates exclude cases not belonging to the target population through ‘terminating events’ such as deaths, institutional moves (refresher sample only) and moves out of Great Britain (or England for refresher sample). Fieldwork response rates are covered first and then key study response rates are presented.<sup>3</sup> Respondents are defined as those who gave a full or partial interview either in person or by proxy.

## Fieldwork response rates

Three different types of fieldwork response rate are presented here. Household contact rates,<sup>4</sup> individual cooperation rates<sup>5</sup> and individual response rates<sup>6</sup> are measures often used to evaluate the quality of fieldwork. External information from the NHS Central Register was matched to non-respondents to identify any deaths that had not been revealed in the course of fieldwork. Individuals whose outcome showed that their eligibility had *not* been confirmed during fieldwork were all assumed to be eligible for the response rate calculation (for non-contacts, movers etc.).

For all Cohort 1 households issued at wave 6, the household contact rate was 98.3%. Amongst Cohort 1 core members, an individual cooperation rate of 86.3% was achieved and the overall response rate for Cohort 1 core members was 84.8%. Table 5.9 shows the reasons for non-response for Cohort 1 core members in wave 6.<sup>7</sup>

The equivalent household contact rate for Cohort 3 was 96.7%. The individual cooperation rate for Cohort 3 core members was 83.9% and their overall response rate was 81.5%. Table 5.10 shows the reasons for non-response for Cohort 3 core members in wave 6.

---

<sup>3</sup> Additional types of study response rate will also be included in the wave 6 technical report.

<sup>4</sup> The contact rate is defined as ‘total households where contact was made with at least one member of the sample divided by total eligible households’.

<sup>5</sup> The cooperation rate is defined as ‘total individual wave 6 respondents divided by total eligible individuals contacted by the interviewer’. Non-contacts and those untraced are therefore also treated as ineligible in this response rate.

<sup>6</sup> The response rate is defined as ‘total individual respondents to wave 6 divided by total individuals eligible for wave 6’. By eligible, we mean that core members were *not* known to have died, moved into an institution (refresher sample only) or moved outside Great Britain (outside England for refresher sample). Note that inclusion in either the numerator or denominator was *not* conditional upon response at wave 5. Hence the total respondents in wave 6 included those core members who returned to the study after missing wave 5.

<sup>7</sup> All core members had an interview at the first wave, but their pattern of response at subsequent waves differs amongst this group.

The equivalent household contact rate for Cohort 4 was 97.5%. The individual cooperation rate for Cohort 4 core members was 85.2% and their overall response rate was 83.2%. Table 5.11 shows the reasons for non-response for Cohort 4 core members in wave 6.

The equivalent household contact rate for Cohort 6 was 88.9%. The individual cooperation rate for Cohort 6 core members was 61.5% and their overall response rate was 54.7%. Table 5.12 shows the reasons for non-response for Cohort 6 core members in wave 6.

Note: Last column may not add up to 100% because of rounding.

As in previous waves, the largest component (ranging from 70% in Cohort 6 to 82% in Cohort 4) of non-response within each of the cohorts was a result of refusals. A judgement of the impact of any differential non-response is reserved for Section 5.7, where bias is examined.

### Study response rates

As with the field response rates, study response rates exclude cases not belonging to the target population through ‘terminating events’ such as deaths, institutional moves (refresher sample only) and moves out of Great Britain (or England for refresher sample). Two key types of study response rates are presented here for each cohort: the (cross-sectional) wave 6 response rates conditional upon baseline wave and the (longitudinal) conditional wave 6 response rates.

#### *The (cross-sectional) wave 6 response rate conditional upon baseline wave*

##### *Cohort 1*

A total of 11,391 original core members were interviewed at wave 1. Table 5.13 shows the status of these core members at wave 6.

In order to work out the proportion of eligible Cohort 1 core members interviewed at wave 6, the following response rate was calculated as conditional upon response in wave 1 (of those who were still eligible). However, inclusion in either the numerator or denominator was *not* conditional upon response in any subsequent wave. Hence the total number of respondents in wave 6 includes those who returned to the ELSA study at wave 6 after missing up to four prior waves. The (cross-sectional) wave 6 response rate conditional on response at wave 1 was 66.2%.

**Table 5.13. Status of original Cohort 1 core members (C1CMs) at wave 6**

	Frequency	%
Died	2,682	24
Moved out of Great Britain	157	1
Respond at wave 6	5,659	50
Non-respond at wave 6	2,893	25
<i>Unweighted N</i>	<i>11,391</i>	<i>100</i>
<i>Total C1CMs eligible at wave 6</i>	<i>8,552</i>	
<i>Total C1CMs ineligible at wave 6</i>	<i>2,839</i>	
<b>STUDY RESPONSE RATE</b>	<b>5,659 / 8,552</b>	<b>66.2</b>

Note: Last column may not add up to 100% because of rounding.

##### *Cohort 3*

Wave 3 represents the baseline wave of ELSA for core members belonging to Cohort 3. A total of 1,276 Cohort 3 core members took part at wave 3. Table 5.14 shows the status of these core members at wave 6.

The wave 6 response rate conditional upon response at wave 3 reflects the proportion of core members from Cohort 3 with a wave 6 interview (of those who were still eligible). A response rate of 71.8% was achieved for Cohort 3 core members at wave 6.

**Table 5.14. Status of original Cohort 3 core members (C3CMs) at wave 6**

	Frequency	%
Died	26	2
Moved out of Great Britain	14	1
Respond at wave 6	888	70
Non-respond at wave 6	348	27
<i>Unweighted N</i>	1,276	100
<i>Total C3CMs eligible at wave 6</i>	1,236	
<i>Total C3CMs ineligible at wave 6</i>	40	
<b>STUDY RESPONSE RATE</b>	<b>888 / 1,236</b>	<b>71.8</b>

Note: Last column may not add up to 100% because of rounding.

#### *Cohort 4*

Wave 4 represents the baseline wave for Cohort 4 core members. A total of 2,290 Cohort 4 core members took part at wave 4. Table 5.15 shows the status of these core members at wave 6.

The wave 6 response rate conditional upon response at wave 4 reflects the proportion of core members from Cohort 4 with a wave 6 interview (of those who were still eligible). A response rate of 81.8% was achieved for Cohort 4 core members at wave 6.

**Table 5.15. Status of original Cohort 4 core members (C4CMs) at wave 6**

	Frequency	%
Died	82	4
Moved out of Great Britain	13	1
Respond at wave 6	1,796	78
Non-respond at wave 6	399	17
<i>Unweighted N</i>	2,290	100
<i>Total C4CMs eligible at wave 6</i>	2,195	
<i>Total C4CMs ineligible at wave 6</i>	95	
<b>STUDY RESPONSE RATE</b>	<b>1,796 / 2,195</b>	<b>81.8</b>

Note: Last column may not add up to 100% because of rounding.

#### *The (longitudinal) conditional wave 6 response rate*

The longitudinal response rate shows the proportion of core members who have been interviewed at every wave of the study from those who were eligible at each wave. This group is selected for longitudinal analysis. The longitudinal conditional rate for core members at wave 6 was 55.7% for Cohort 1, 63.2% for Cohort 3 and 78.5% for Cohort 4.

### **Profile of main interview respondents at wave 6**

#### *Cohort 1*

The profile of core member respondents belonging to Cohort 1 (born on or before 29 February 1952) is presented in Table 5.16; this includes respondents who took part in all six waves plus some who returned to wave 6 after missing

waves 2, 3, 4 and/or 5.<sup>8</sup> The distribution shows that the sample contains more women than men, as expected.

Table 5.17 is based on Cohort 1 core members who had taken part in all of waves 1 to 5 and shows their main interview response at wave 6. Amongst those who were still eligible at wave 6 (i.e. had not died or moved out of Great Britain), the propensity to participate at wave 6 decreased with age for both men and women.

**Table 5.16. Achieved sample of Cohort 1 core members, by age in 2012–13 and sex**

*Respondents in 2012–13, including proxies but excluding those in institutions*

	Men	Women	Total	Men	Women	Total

<i>Women</i>	<i>1,247</i>	<i>1,294</i>	<i>326</i>	<i>2,867</i>

Note: Columns may not add up to 100% because of rounding.

<sup>8</sup> Interviewers do not follow up sample members who have repeatedly refused or if comments recorded at their last visit suggest it would be unwise to return.

**Cohort 3**

The profile of the core member respondents belonging to Cohort 3 is presented in Table 5.18. As with Cohort 1, the achieved sample of Cohort 3 core members at wave 6 contains more women than men. The age distribution of the Cohort 3 core member sample is not evenly distributed across the ages represented, with fewer sample members being in the youngest and oldest age year.

**Table 5.18. Achieved sample of Cohort 3 core members, by age in 2012–13 and sex**

*Respondents in 2012–13, including proxies but excluding those in institutions*

	Men	Women	Total	Men	Women	Total

Note: Columns may not add up because of rounding.

**Profile of proxy respondents**

Proxy interviews were carried out if an ELSA panel member could not be interviewed in person because of a physical or cognitive impairment, or if they were away in hospital or temporary care, or if they had refused a personal interview but were happy for a proxy to answer for them. Not including institutional interviews, a total of 323 proxy interviews were carried out at wave 6 with core members across all cohorts. Of these, 216 were with Cohort 1 members. Table 5.21 shows the proxy sample in 2012–13 for Cohort 1 core members, by age and sex. There were more proxy interviews for men in the sample than for women (53% compared with 47%).

**Table 5.21. Proxy interview sample (Cohort 1), by age in 2012–13 and sex**

*Sample members requiring a proxy in 2012–13, excluding those in institutions*

	Men	Women	Total	Men	Women	Total
<b>Age in wave 6</b>				%	%	%

<i>Unweighted N</i>	<i>114</i>	<i>102</i>	<i>216</i>	<i>53</i>	<i>47</i>	<i>100</i>

Note: Columns may not add up because of rounding.

## Profile of nurse interview respondents

In total, 8,054 nurse visits were completed at wave 6. ELSA core members were eligible for the nurse visit if they had completed an ELSA wave 6 main interview in person (and not by proxy). 7,730 nurse visits were carried out with eligible core members and 323 were carried out with partners.<sup>9</sup> Although not strictly eligible, partners were allowed a nurse visit if it would facilitate their future participation in the study. Among core members who had an in-person interview, and were thus eligible for the nurse visit, the response rate was 88%. The age–sex profile of nurse visit respondents is shown in Table 5.22 and achieved nurse visits by age are shown in Table 5.23.

**Table 5.22. Achieved nurse visits with core members from all cohorts, in 2012–13, by age and sex**

	Men	Women	Total	Men	Women	Total
<b>Age in wave 6</b>				%	%	%
50–54	225	278	503	3	4	7
55–59	532	660	1,192	7	9	15
60–64	666	843	1,509	9	11	20
65–69	692	811	1,503	9	10	19
70–74	506	603	1,109	7	8	14
75–79	447	558	1,005	6	7	13
80–84	217	294	511	3	4	7
85+	163	235	398	2	3	5
<i>Unweighted N</i>	3,448	4,282	7,730	45	55	100

Note: Columns may not add up because of rounding.

**Table 5.23. Achieved nurse visits with core members from all cohorts as a percentage of wave 6 interviews (2012–13), by age**

	Productive wave 6 interview (excluding proxies)	Productive wave 6 nurse visit	% of wave 6 interviews resulting in a nurse visit
<b>Age in wave 6</b>			
50–54	620	503	81
55–59	1,375	1,192	87
60–64	1,673	1,509	90
65–69	1,673	1,503	90
70–74	1,236	1,109	90
75–79	1,125	1,005	89
80–84	602	511	85
85+	482	398	83
<i>Unweighted N</i>	8,786	7,730	88

<sup>9</sup> One of the nurse visits was carried out with someone who was ineligible and is not included in the tables below.

A number of reasons were given for not taking part in the nurse visit. The main reason was refusal (see Table 5.24). A minority did agree to take part but could not be contacted by the nurse. This may reflect some people’s circumstances, but in other cases this could be interpreted as an implicit refusal despite the fact that consent had been given to be visited by the nurse at the end of the main interview. Other reasons for non-response include being too ill or away at the time.

**Table 5.24. Reasons for non-response to nurse visit for core members from all cohorts**

*Core members who responded to wave 6 interview in person, but had no nurse visit*

	Frequency	%
Non-contact	50	5
Refusal	809	77
Other	197	19
<i>Unweighted N</i>	<i>1,056</i>	<i>100</i>

Note: Last column may not add up to 100% because of rounding.

## 5.7 Implications for analyses: weighting

This section describes the weighting strategies used to adjust for non-response and the process of combining Cohorts 1, 3, 4 and 6. We describe the cross-sectional and longitudinal weights constructed at wave 6, beginning with the longitudinal weights. We then describe additional weights calculated for the self-completion questionnaire, nurse visit and blood sample.

### Longitudinal weights

For those core members from Cohort 1 eligible for the main interview in wave 6, *and* who responded at all previous waves, response to wave 6 was modelled using logistic regression analysis on a range of household- and individual-level information collected at wave 5 (supplemented by information taken from waves 1 to 4). The analysis was conducted using the longitudinal weight derived in wave 5 to ensure that the wave 6 weight did not replicate the adjustments made by the wave 5 weight.

The results showed significant differences between respondents and non-respondents on a number of characteristics:

- age (at wave 1) by sex;
- government office region;
- number in household;
- whether had a long-term limiting illness;
- white/non-white ethnicity;
- self-reported general health.

A longitudinal weight was calculated for the set of 4,711 core members who responded to all six waves of ELSA and remain living in private households. The weighting strategy in wave 6 aimed to minimise any bias arising from sample loss after wave 5. The longitudinal weight aims to be representative of

those living in England at a single point in time (i.e. at wave 1 in 2002–03), so those who subsequently move to Scotland or Wales are still assigned a longitudinal weight.

Taking the inverse of the estimated probability of response (from the logistic regression model) created a non-response weight for wave 6. This was then multiplied by the wave 5 longitudinal weight (and scaled to an average of 1) to produce the wave 6 longitudinal weight. The sequential nature of the weighting<sup>10</sup> means that we have adjusted for non-response to HSE and each of the six waves of ELSA.

### Cross-sectional weights

A cross-sectional weight was derived that can be used to analyse all core members responding at wave 6. This allows for the inclusion of Cohort 3, Cohort 4 and Cohort 6 core members including ‘wave non-responders’ (those core members from Cohorts 1, 3 and 4 who returned to the study at wave 6 after missing one or more previous waves). The cross-sectional sample at wave 6 aims to be representative of those living in England in 2012–13. As described below, we weight to population estimates for England, so by definition we cannot (and do not) include anyone now living in Scotland or Wales in the cross-sectional weighting.

Core members responding at wave 6 can be described as the *combined sample*. For weighting purposes, this combined sample was split into two main groups by age (at interview): those aged 61+ and those aged 50–60. The cross-sectional weight was calculated using the following steps:

1. Non-response to wave 6 was analysed for Cohort 3 core members who had responded to all previous waves (3 to 5). The response rate amongst those eligible was found to be very high (93%); therefore an adjustment for non-response between waves 5 and 6 was not judged to be necessary.
2. A non-response weight was derived for Cohort 4 core members who had responded to both waves 4 *and* 5 to adjust for non-response between waves 5 and 6.
3. A non-response weight was derived for Cohort 6 core members to adjust for non-response at wave 6.
4. Population estimates for core members aged 61+ at wave 6 were derived from the longitudinal group (those Cohort 1 core members responding to all five previous waves of ELSA) combined with Cohort 4 core members aged 61+.
5. The non-response weights for *all* core members aged 61+ at wave 6 (i.e. the two groups mentioned above in point 4 plus wave non-responders) were then calibrated to these population estimates plus estimates of

---

<sup>10</sup> Longitudinal weights are based on a sequence of attrition models, one for each wave. Each time, the resulting non-response weight is multiplied by the weight created at the previous wave. In this case, the weight derived in wave 6 builds on the wave 5 weight, which, in turn, built on the weight created in wave 4 etc.

age/sex and region from 2012 household population estimates for England.<sup>11</sup>

6. The non-response weights for all core members aged 50–60 at wave 6 were calibrated to 2012 population estimates of age/sex and region for England.<sup>12</sup>
7. Finally, the calibration weights from steps 5 and 6 above were combined and scaled so that the average weight was equal to 1.

These steps are discussed in turn. A more detailed description will be provided in the wave 6 technical report.

#### ***Non-response weights for Cohort 4***

For the 1,932 Cohort 4 core members eligible for the main interview in wave 6 who responded to waves 4 *and* 5 (and remaining in private households in England), response to wave 5 was modelled on a range of household- and individual-level information collected at wave 5. The analysis was conducted using the non-response weight derived in wave 5 to ensure that the wave 6 weight did not replicate any adjustment made by the wave 5 weight.

The results showed significant differences between respondents and non-respondents on a number of characteristics:

- age by sex;
- government office region;
- white/non-white ethnicity;
- housing tenure.

Taking the inverse of the estimated probability of response created a non-response weight to adjust for potential non-response bias between wave 6 and wave 5 for a total of 1,775 respondents.

#### ***Non-response weights for Cohort 6***

A cohort of people born between 1 March 1956 and 28 February 1962 was added to the ELSA sample at wave 6. They were selected from the Health Survey for England 2009, 2010 and 2011 and are collectively referred to as Cohort 6. This group can be seen as comprising two distinct cohorts:

- those born between 1 March 1960 and 28 February 1962 (aged 50–51 at point of sampling for wave 6), otherwise known as the refresher sample;
- those born between 1 March 1956 and 29 February 1960 (aged 52–55 at point of sampling for wave 6), thereby providing a ‘top-up’ of Cohort 4 core members.

Their response to wave 6 was modelled on a range of household- and individual-level information collected from HSE. The results showed significant differences between respondents and non-respondents on a number of characteristics:

---

<sup>11</sup> Age is defined here as age at 1 March 2012, immediately prior to the beginning of wave 6 fieldwork.

<sup>12</sup> Again age is defined as age at 1 March 2012.

- sex;
- government office region;
- marital status;
- household type;
- National Statistics socio-economic classification (NS-SEC);
- housing tenure.

Taking the inverse of the estimated probability of response created a non-response weight to adjust for potential non-response bias between HSE and ELSA.

### *Cross-sectional weights for those aged 61+*

Core members aged 61+ responding at wave 6 belonged to one of three groups:

- 1) Cohort 1 core members who had taken part in all five previous waves of ELSA;<sup>13</sup>
- 2) Cohort 4 core members who took part in waves 4, 5 and 6;<sup>14</sup>
- 3) wave non-responders: core members from Cohorts 1 and 4 who had returned to the study at wave 6 after missing one or more previous waves.<sup>15</sup>

It is often speculated that wave non-responders are likely to have different characteristics from those who have taken part at all waves (Lynn et al., 1994). At wave 3, it was found that the following socio-demographic features were predictive of wave non-response when compared with response to all waves:

- housing tenure;
- white/non-white ethnicity;
- highest educational qualifications;
- marital status.

In order to combine the three groups to create a representative sample of persons aged 61+, it was necessary to make sure, as far as possible, that the characteristics of the combined sample match those of the population. In order to do this, estimates of population characteristics were required.

The first two groups already had weights derived to adjust for non-response at wave 6, previous waves of ELSA and HSE. Combining these groups provided a basis from which to estimate the population characteristics of those aged 61+. Before these estimates could be derived, two adjustments were necessary:

- i) the non-response weights of those aged 61–78 were scaled down so that this group was in the correct proportion as compared with those aged 79 and over;

---

<sup>13</sup> Ten of these respondents had moved to either Wales or Scotland and were therefore given zero cross-sectional weights.

<sup>14</sup> Three of these respondents had moved to Scotland and were therefore given zero cross-sectional weights.

<sup>15</sup> Thirteen of these respondents had moved to either Wales or Scotland and were therefore given zero cross-sectional weights.

- ii) these weights were then calibrated to mid-2012 household population estimates of age/sex and region.

Estimates of housing tenure, white/non-white ethnicity, highest educational qualifications and marital status were then derived from the combined groups weighted by the resulting weights (the same characteristics were used as in waves 3, 4 and 5 for consistency).

The non-response weights for *all* core members aged 61+ at wave 6 (i.e. the two groups already combined plus the third group of wave non-responders) were then adjusted using calibration weighting so that the resulting weights, when applied to the three groups combined, provide a sample profile that matches the population estimates on the four socio-demographic characteristics plus estimates of age/sex and region of those aged 61+ (from mid-2012 household population estimates – see Table 5.25).

**Table 5.25. Household population estimates**

*Mid-2012 England household population (aged 50 and over)*

Age	Men	Women	Total	Men %	Women %	Total %
50–55	2,050,897	2,090,789	4,141,686	23.7	21.8	22.7
56–60	1,464,948	1,506,869	2,971,817	16.9	15.7	16.3
61–64	1,184,208	1,237,611	2,421,819	13.7	12.9	13.3
65–69	1,348,159	1,425,084	2,773,243	15.6	14.8	15.2
70–74	962,314	1,068,591	2,030,905	11.1	11.1	11.1
75–79	763,262	905,061	1,668,323	8.8	9.4	9.1
80–84	519,555	705,401	1,224,956	6.0	7.3	6.7
85+	368,560	663,714	1,032,274	4.3	6.9	5.7
Total	8,661,903	9,603,120	18,265,023	100	100	100

Source: Calculated from ONS, Annual Mid-Year Population Estimates for England and Wales, 2012, <http://www.ons.gov.uk/ons/rel/pop-estimate/population-estimates-for-england-and-wales/mid-2012/mid-2012-population-estimates-for-england-and-wales.html>.

### ***Cross-sectional weights for those aged 50–60***

Responding core members aged 50–60 at wave 6 came from Cohorts 3, 4 and 6.<sup>16</sup> These groups were combined and their non-response weights were adjusted using calibration weighting so that the resulting weights provide a sample profile that matches population estimates of age/sex and region (from mid-2012 household population estimates) for those aged 50–60.

### ***Putting the cross-sectional weights together***

The final step in the calculation of the cross-sectional weights was to take the calibrated weights from the two groups (50–60 and 61+) combined and to scale them so that they are in the correct proportion in the final weighted sample. The final weights were then scaled so that the average weight was equal to 1.

<sup>16</sup> Three of these respondents had moved to Wales and were therefore given zero cross-sectional weights.

**Table 5.26. Achieved (combined) sample of core members, by age in 2012–13 and sex***Respondents in 2012–13, including proxies but excluding those in institutions*

	Men	Women	Total	Men	Women	Total
Age at wave 6 interview				%	%	%
50–55	1,018	1,038	2,056	23.7	21.8	22.7
56–60	727	748	1,475	16.9	15.7	16.3
61–64	588	614	1,202	13.7	12.9	13.3
65–69	669	708	1,377	15.6	14.8	15.2
70–74	478	531	1,008	11.1	11.1	11.1
75–79	379	449	828	8.8	9.4	9.1
80–84	258	350	608	6.0	7.3	6.7
85+	183	330	512	4.3	6.9	5.7
<i>Weighted N</i>	<i>4,300</i>	<i>4,768</i>	<i>9,068</i>	<i>100</i>	<i>100</i>	<i>100</i>
<i>Unweighted N</i>	<i>4,042</i>	<i>5,026</i>	<i>9,068</i>	<i>100</i>	<i>100</i>	<i>100</i>

Note: Columns may not add up to 100% because of rounding.

The profile of the combined core member respondents, weighted by the cross-sectional weight, is presented in Table 5.26.

### Self-completion weights

For the 9,068 core members living in private households in England who completed a full or partial wave 6 main interview in person or by proxy, response to the main self-completion questionnaire was modelled on a range of household- and individual-level information collected from the ELSA wave 6 main interview. In a separate exercise, response to the sexual activities self-completion questionnaire was modelled using the same data. The weighting strategy aimed to minimise any bias arising from differential non-response to each self-completion questionnaire. The analyses were conducted on data weighted by the wave 6 cross-sectional weight.

### Main self-completion weights

The results for the main self-completion questionnaire showed significant differences between core member respondents to the main self-completion and non-respondents on a number of characteristics:

- age by sex;
- government office region;
- highest educational qualifications;
- white/non-white ethnicity;
- housing tenure;
- self-reported general health;
- whether had a long-term limiting illness;
- number in household;
- financial unit type;
- current work/activity status;
- whether had help with showcards.

A non-response weight for the 7,903 self-completion respondents was created by taking the inverse of the estimated probability of response. The final self-completion weight was a product of this non-response weight and the wave 6 cross-sectional weight.

### ***Sex self-completion weights***

The results for the sexual activity self-completion questionnaire showed significant differences between core member respondents to the sexual activity self-completion and non-respondents on the following characteristics:

- age by sex;
- government office region;
- highest educational qualifications;
- white/non-white ethnicity;
- marital status;
- self-reported general health;
- whether had help with showcards.

A non-response weight for the 6,201 respondents to the sex self-completion was created by taking the inverse of the estimated probability of response. The final sex self-completion weight was a product of this non-response weight and the wave 6 cross-sectional weight.

### ***Nurse visit and blood sample weights***

#### ***Nurse visit weights***

For the 9,068 core members living in private households in England who completed a full or partial wave 6 main interview in person or by proxy, response to the nurse visit was modelled on a range of household- and individual-level information collected from the ELSA wave 6 main interview. The weighting strategy aimed to minimise any bias arising from differential non-response to the nurse visit. The analysis was conducted on data weighted by the wave 6 cross-sectional weight.

The results showed significant differences between core member respondents to the nurse visit and non-respondents on a number of characteristics:

- age by sex;
- government office region;
- highest educational qualifications;
- white/non-white ethnicity;
- marital status;
- self-reported general health;
- whether had a long-term limiting illness;
- financial unit type;
- current work/activity status;
- frequency of taking part in mildly energetic activities;
- self-reported hearing;
- whether ever smoked.

A non-response weight for the 7,699 respondents with a nurse visit was created by taking the inverse of the estimated probability of response. The

final nurse visit weight was a product of this non-response weight and the wave 6 cross-sectional weight.

### ***Blood sample weights***

For the 7,699 core members living in private households in England who took part in the nurse visit, response to the blood sample was modelled on a range of household- and individual-level information collected from the ELSA wave 6 main interview. The weighting strategy aimed to minimise any bias arising from differential non-response in provision of a blood sample. The analysis was conducted on data weighted by the wave 6 nurse weight.

The results showed significant differences between core member respondents to the blood sample and non-respondents on a number of characteristics:

- age by sex;
- government office region;
- highest educational qualifications;
- white/non-white ethnicity;
- self-reported general health;
- whether had a long-term limiting illness;
- financial unit type;
- whether has children and whether they are living with them or not;
- frequency of taking part in vigorous activities;
- frequency of taking part in mildly energetic activities;
- current work/activity status.

A non-response weight for the 6,180 respondents with a blood sample was created by taking the inverse of the estimated probability of response. The final blood sample weight was a product of this non-response weight and the wave 6 nurse weight.

## **5.8 Conclusions**

This chapter aimed to provide an overview of the survey methodology for ELSA wave 6. The main topics included sample design, interview content, field and study response rates, and weighting of the data.

The format of the ELSA interview itself has remained relatively unchanged over time, with interviews every two years and nurse visits every four years. Over the waves, ELSA interviewers have consistently worked hard to maintain the panel of ELSA sample members. At wave 6, household contact rates of over 96% were achieved for all three existing ELSA cohorts and 89% for the wave 6 refresher cohort.

The prior experiences of sample members within each cohort need to be considered when interpreting response rates at wave 6. For Cohort 1 members, this was the sixth ELSA interview they had been asked to do. Cohort 3 members joined ELSA at wave 3 (so wave 6 represented their fourth wave of ELSA interviewing), and wave 6 was the third interview for Cohort 4 members. Levels of non-response do tend to accumulate over time as further waves of interviewing are conducted and, as expected, higher study response rates were found at wave 6 amongst those existing members who joined ELSA

most recently (Cohort 4). Response among those who had taken part at the first wave they were invited to and were still believed to be eligible at wave 6 were 66.2% for Cohort 1, 71.8% for Cohort 3 and 81.8% for Cohort 4. It was therefore important to present the response rates separately for each cohort rather than just producing combined rates.

Fifty-eight per cent of all wave 6 interviews were with those belonging to Cohort 1 and 53% were with Cohort 1 core members. Original core members from wave 1 are still found to be highly committed to the study. Their fieldwork response rate showed that 84.8% of those issued to field (and still found to be eligible) had a wave 6 interview. There is a wealth of data accumulating for this group, with 55.7% of eligible Cohort 1 core members having been interviewed at every wave (the longitudinal study response rate).

Cohort 3 sample members made up 12% of the total achieved sample at wave 6 and Cohort 3 core members made up 8% of the achieved sample at wave 6. They were introduced to ELSA at wave 3 to ‘refresh’ the younger age group and help ensure the study remained representative of all those aged 50 and over. The fieldwork response rates for Cohort 3 core members were slightly lower than for Cohort 1 (81.5% and 84.8%, respectively). Sixty-four per cent (63.5%) of Cohort 3 members who took part in an initial interview at wave 3 have taken part in every wave since they joined the study.

Cohort 4 accounts for 19% of achieved interviews at wave 6 (and core members from Cohort 4 account for 17%) covering sample members aged 54 to 78 at point of sampling for wave 6. This cohort had a higher study response rate than the two other existing cohorts but a similar fieldwork response rate (83.2%). Their cross-sectional study response rate (conditional upon baseline wave) was 81.8%, compared with 71.8% and 66.2% in Cohorts 3 and 1, respectively. Seventy-nine per cent (78.5%) of Cohort 4 members who took part in an initial interview at wave 4 have taken part in every wave since they joined the study.

Cohort 6 was introduced at wave 6 and accounts for 11% of the achieved interviews at wave 6 (core members from Cohort 6 account for 8% of the achieved interviews). This cohort was introduced to refresh the younger end of the sample. The team will continue to work hard to ensure that this group and others within the wider sample remain engaged with the study to ensure that the sample remains representative. Study and longitudinal response rates are not applicable to the refresher cohort. The fieldwork response rate was 54.7% for Cohort 6.

For all the cohorts, refusals made up the biggest component of non-response at wave 6. To help combat longer-term drop-out, most will be encouraged back to the study at wave 7.

The response rates in this chapter provide useful indicators of the success of panel maintenance. However, it is also important to investigate the impact of any differential non-response, i.e. whether those with certain characteristics were more likely to respond than others. The section on weighting highlights how we attempt to minimise any bias arising from sample loss after each wave. Key characteristics of non-respondents and respondents are presented, and a summary is given of how the longitudinal and cross-sectional weights at

wave 6 were constructed. The process of combining Cohorts 1, 3, 4 and 6 to facilitate cross-sectional analysis of all core members at wave 6 is also described.

Over time, the ELSA study team intends to use information about differential non-response to help inform fieldwork practices and develop the strategies needed to maximise participation by those groups most at risk of attrition. Our experience with the Cohort 6 refresher sample at wave 6 has informed the redesign of introductory letters and the monitoring of response at wave 7.

# E. Economics domain tables

Zoë Oldfield *Institute for Fiscal Studies*

## Introduction

E.1 This chapter presents selected data tables from the Economics domain of the English Longitudinal Study of Ageing. The tables are split into two main sections. The first section presents cross-sectional data from Wave 6 of ELSA, which took place from May 2012 to May 2013. The second section presents results that make use of the longitudinal aspect of the ELSA data.

E.2 Both main sections are further divided into three subsections, each containing information on income, pensions, wealth and other measures of resources, and labour market participation.

E.3 The variables included in each table have been selected to provide a broad picture of the data available from the Economics domain of ELSA. A glossary of the measures is provided in the annex to this chapter.

E.4 The unit of observation in all tables is the individual. All cross-sectional tables are based on the cross-section of ELSA sample members in wave 6 of the data. This includes refreshment sample members. All longitudinal tables are based on individuals who have responded in all of waves 1 to 6 (the ‘balanced panel’) unless otherwise specified. All numbers are based on weighted data. Both unweighted and weighted frequencies (N) are reported. For cross-sectional analyses, cross-sectional weights are used. For longitudinal analyses, longitudinal weights are used. All values are expressed in January 2013 prices using the retail price index (RPI).

## Cross-sectional tables

### Income

E.5 Table E1a shows mean *unequalised* net weekly family income by age and family type. As with all tables in this report, the unit of observation is the individual but each individual is assigned the income level of their family (where a family is defined as a couple or a single person and any dependent children they may have). Table E1b shows mean *equalised* net weekly family income by age and sex.

E.6 Equivalising income is one way to compare income across different family types. A couple will need more income than a single person to be equally well off but, because of economies of scale involved with sharing, they will not need twice as much income to be as well off. Although equivalising is useful in making comparisons across different family types, the process of equivalising means that assumptions have to be made about the extent of economies of scale and there are many different equivalence scales that could be used. For this reason, Table E1a shows numbers that are unequalised so that it is possible to see the actual level of income unadjusted for household size.

E.7 The unequivalised numbers in Table E1a are grouped into family types so that comparisons can be made across age groups *within* household types. Tables E1a and E1b look at mean total income and also disaggregate income into some broad components: employment income, self-employment income, private pension income, state pension income, state benefit income, asset income and other income. Table E1b groups individuals into groups defined by age and sex.

E.8 Looking at all family types, Table E1a reveals that mean net unequivalised income is £559.41 per week. Converting all values to an equivalent-adult basis, Table E1b reveals that mean net equivalised income is £395.19 per week. At younger ages, employment income is the biggest component of total income, whereas at older ages private and state pension income becomes much more important.

E.9 Tables E2a and E2b look at the distribution of total net weekly family income. In a similar way to Tables E1a and E1b, Table E2a looks at the distribution of total *unequivalised* income by age and family type and Table E2b looks at the distribution of total *equivalised* income by age and sex. The first column of numbers reports the mean income level and the remaining columns report various percentile points including the median level.

### **Pensions, wealth and other measures of resources**

E.10 Income is just one way to measure financial resources and, particularly in the older population, other resources may be important. This subsection looks at financial wealth, private pension membership, household spending and a measure of adequacy of financial resources in the future.

E.11 Table E3 looks at average (mean and median) wealth by age and family type. Total net (non-pension) wealth is reported along with some broad components of wealth: net financial wealth, net physical wealth (including secondary housing) and net primary housing wealth. Table E4 looks at the mean of total net (non-pension) wealth along with various percentile points by age and family type. Primary housing wealth makes up the largest component of total (non-pension) wealth for all groups. There is a large amount of dispersion in the total wealth distribution. Looking at single women aged 55–59, for example, Table E4 reveals that 25% of this group have £400 or less of total wealth while 25% have £200,700 or more. The wealth distribution is much more unequal than the total income distribution. The ratio of the 75<sup>th</sup> percentile to the 25<sup>th</sup> percentile of income for all individuals (Table E2b) is 2.2, meaning that the income of the person at the 75<sup>th</sup> percentile point is 2.2 times larger than the income of the person at the 25<sup>th</sup> percentile point. In contrast, the ratio of the 75<sup>th</sup> percentile to the 25<sup>th</sup> percentile of total wealth for all individuals (Table E4) is 4.2.

E.12 Tables E5a and E5b look at private pension membership (pensions from all non-state sources). Private pension wealth can be an important potential source of resources for the older population and private pension membership is a useful proxy for private pension wealth. Table E5a looks at private pension membership by age and sex for all workers and non-workers under the state pension age (SPA) and Table E5b reports similar numbers for workers only. The first column of numbers in Tables E5a and E5b report the percentage of individuals who are members of a private pension scheme. The next three columns of numbers break this figure down into those who are currently contributing to a private pension scheme, those who are receiving income from a private pension scheme and those who have retained rights in a private pension

scheme. Because individuals can have multiple pensions at different stages of contribution, receiving income and retaining rights, these three columns of numbers do not sum to the total percentage of individuals who are members of a private pension scheme. The numbers show, for example, that 79% of men (workers and non-workers) aged 50–SPA are currently members of at least one private pension scheme. Breaking that down further, the numbers show that 43% of men aged 50–SPA are currently contributing to at least one private pension scheme, 29% are receiving an income from at least one private pension scheme and 30% have retained rights in at least one private pension scheme.

E.13 The next measure of resources that we report is household spending. This measure may be a more useful indication of the level of resources available for a household than income, because consumption tends to be smoothed across time. A retired household may have low income but may be drawing down assets in order to fund its consumption. Table E6 looks at the level of spending on some very broad types of goods and services by age and family type. Note that there are some large outliers in the level of spending on transfers outside the home which, combined with relatively small sample sizes, push up the level of the mean in some groups (notably single women aged 70–74 and 75–79), so any patterns in transfer expenditure should be interpreted with caution.

E.14 Current resources give us a useful picture of economic well-being, but respondents may be aware of other issues that might determine how well off they feel or how well off they expect to be in the future. For example, a respondent may have health issues that might affect their future expected resources; or they may be expecting to help in the care of elderly parents, which again might reduce their future expected resources. Using the expectations question methodology (see definition in the annex to this chapter), respondents are asked to report the chances that they will have insufficient resources at some point in the future to meet their needs, where a higher number indicates a higher chance of having insufficient resources. The results are reported by age, sex and income group in Table E7. Because expectations are asked on an individual basis, we split couples into ‘partnered men’ and ‘partnered women’ so that we can look at differences between men and women in couples. For most age and income groups (the oldest and the youngest age groups being the notable exceptions), partnered women are more pessimistic, on average, than their male counterparts despite having access to the same resources. Single women are often more pessimistic than their male counterparts on average, although they may have good reason to expect to have insufficient resources given that they have lower incomes on average, as Table E1a shows.

### **Labour market participation**

E.15 The tables in this subsection look at different aspects of labour market participation. Table E8 looks at the percentage of respondents working full-time, part-time or either full- or part-time by age, sex and wealth group. We restrict our sample to those aged less than 75 years.

E.16 Using the expectations question methodology (see definitions), Table E9 reports the mean chances of working at future ages. The age that respondents are asked to consider in thinking about their chances of working depends on their current age. The first column of numbers shows the ‘target age’ for each age group. For example, men aged 50–59 are asked about the chances of working at age 60, while women aged 50–54 are asked about the chances of working at age 55. The second

column of numbers reports the mean chances within each age and sex group. The five columns on the right-hand side report the mean chances within each age, sex and wealth group.

E.17 Health is an important factor in an individual's ability to work. Respondents are asked whether they have a health problem that limits the kind or amount of work they can do. If respondents are currently working and they report that they do have a health problem that limits the kind or amount of work they can do, they are asked a follow-up question about whether this health problem limits the kind or amount of work they can do in their current job. The results in Table E10 combine the information from these two questions. The first column of numbers shows the percentages of individuals (by age, sex and wealth group) who do not report that they have a limiting health problem and the second column of numbers shows the percentage who do. The next three columns of numbers further break down the group with a health limitation into those who have a limiting health problem but are not currently working, those who have a limiting health problem that does not limit them in their current job and those who have a limiting health problem that does limit them in their current job.

E.18 For example, 22% of men aged 55–59 have a health problem that limits the kind or amount of work they can do. This 22% can be further broken down into 15% who are not working, 4% who are working but whose health problem does not limit them in their current job and 3% who are working and whose health problem does limit them in their current job. The numbers in Table E10 also reveal a stark difference between the lowest and highest wealth groups. Looking at all men aged 50–64, the table shows that of the 44% of men in the lowest wealth group who have a limiting health problem, only 7%  $((1\%+2\%)/44\%)$  are in work. This contrasts with the highest wealth group, where a much lower proportion have a limiting health problem (9%) and, of those who do, 44%  $((2\%+2\%)/9\%)$  are in work. A similar pattern is found for women.

E.19 As well as current health problems, respondents' expectations about the effect of their health on their ability to work in the future may be an important factor in their decision making. Table E11 reports the mean chances that health will limit respondents' ability to work at age 65 by age, sex and wealth group, where a higher number indicates a higher chance that health will limit the respondent's ability to work. This information was collected using the expectations questions methodology (see definitions) for workers aged under 65 only.

## **Longitudinal tables**

### **Income**

E.20 Cross-sectional tables using a series of data from different time periods combine the effect of age, time and differential mortality. For example, looking at cross-sectional data on income over time, it would not be possible to isolate the effect of age on income because we cannot strip out the effect of time or differential mortality (that is, the observation that higher-income individuals tend to live longer than lower-income individuals). Because longitudinal data follow the same individuals over time, by selecting a sample of individuals who are interviewed in every wave we can eliminate the effect of differential mortality.

E.21 Table EL1a takes the set of individuals who have responded in every wave from 1 to 6 (the ‘balanced panel’) and tracks average total family income by age, sex and family type in 2002–03 (the ‘baseline’ year) across time (waves). Tables EL1b–EL1e are identical in structure to Table EL1a but look at the broad components of income instead of total income. Earnings is the sum of employment income and self-employment income. Note that family type may change over time as couples form or dissolve, but an individual is defined in terms of their couple status at baseline. Although income is measured at the family level, because family structure may change we look separately at partnered men and partnered women. Partnered women are more likely to see a change in their family structure due to widowhood.

E.22 Tables EL2a–EL2e are similar to Tables EL1a–EL1e but track income by age and education. Education can be a useful proxy for social status or permanent income.

E.23 Table EL3 looks at a measure of inequality. The measure chosen is the interquartile ratio, which is defined as the size of the 75th percentile of income relative to the 25<sup>th</sup> percentile of income ( $p_{75}/p_{25}$ ). An interquartile ratio of 2.00 would mean that the 75<sup>th</sup> percentile point was twice as large as the 25<sup>th</sup> percentile point of income. A larger number implies a more dispersed distribution of income and higher inequality. In general, Table EL3 shows declining inequality over time for this balanced panel.

### **Pensions, wealth and other measures of resources**

E.24 Tables E5a and E5b looked at private pension membership. But private pension membership at a particular point in time is only part of the story. It is the amount that individuals accumulate in that pension fund that determines its value. As individuals move into or out of employment or their circumstances change, their pension contributions may vary. Table EL4a shows how persistently individuals contribute to their private pensions. The table takes the groups of men and women who are below state pension age at baseline and reports the percentage of men and women who never contribute to a private pension in any of the waves in which they are under state pension age (taking into account the changes to state pension age that came into effect), the percentage who contribute in some waves in which they are under state pension age and the percentage who contribute in all waves in which they are under state pension age. For example, a man aged 60 at baseline would be observed to be under state pension age at waves 2 and 3 (he would be 62 and 64, respectively) but over state pension age in wave 4 (he would be 66). If this individual were observed to be contributing to a private pension in waves 1 and 2 but not in wave 4 (when he is over state pension age), he would be counted as ‘always’ contributing to a private pension. The reason for doing this is to reduce the extent to which not contributing to a private pension is due to leaving the labour market. The table is based on individuals who are aged under state pension age at baseline and who are employed or self-employed at baseline and the proportions are reported by age, sex and (baseline) wealth group.

E.25 Table EL4a shows that a rather low proportion of men contribute to a private pension in all waves in which they are aged under the state pension age. Amongst all men aged 50–64 at baseline, only 30.7% always contribute. Amongst women aged 50–59, 45.8% always contribute. To reduce the effect that leaving the labour market has on pension contributions, we have not included years in which the individual is over state pension age when calculating how many waves an individual has contributed to a private pension. However, it is still the case that some of the

dynamics of pension contributions may be due to exits out of the labour market before the state pension age. So, for example, although a man aged 60 at baseline may have a full contribution history, if he retires at age 62 and therefore stops contributing to his pension he will be counted in Table EL4a as only ‘sometimes’ contributing to a private pension.

E.26 Table EL4b shows an alternative way of looking at the persistency of making private pension contributions that attempts to eliminate employment dynamics as an explanation for private pension contribution dynamics. This table is calculated on a similar basis to Table EL4a except that only those individuals who are employed in all waves that they are below state pension age are included. This means that if an individual is observed not contributing, it is not simply due to the fact that they have left the labour market. Table EL4b shows that even conditioning on being in the labour market in all waves, the proportion who contribute to a private pension in every wave is rather low (46.0% for men aged 50–64 and 54.4% for women aged 50–59).

E.27 An alternative way to assess how well off individuals are is to ask them directly how well they are managing financially. Respondents in ELSA are asked which phrase best describes how they (and their partner) are getting along financially. The question is asked once per family and the response categories are ‘manage very well’, ‘manage quite well’, ‘get by alright’, ‘don’t manage very well’, ‘have some financial difficulties’ and ‘have severe financial difficulties’. Looking at the first three columns of data in Table EL5, anyone who puts themselves into any of the bottom three categories (don’t manage very well, have some financial difficulties, have severe financial difficulties) is defined as ‘Reports having financial difficulty’. These columns report the percentage of single men, single women and couples who never report having financial difficulty, the percentage who sometimes report having financial difficulty and the percentage who report having financial difficulty in every wave (1–6). For example, 81.8% of single men did not report having financial difficulty in any of the five waves, 18.2% sometimes reported having financial difficulties and none of them reported having financial difficulty in every wave.

E.28 The numbers in the next three columns of Table EL5 use the same financial difficulties question but, instead of looking at families who report financial difficulties, they look at how many people report that they are managing very well (those putting themselves into the highest category). Again, the columns report the percentage of single men, single women and couples who never report that they manage very well, the percentage who sometimes report that they manage very well and the percentage who report that they manage very well in every wave (1–6). For example, 8.1% of single men reported in every wave that they manage very well, 54.6% sometimes reported managing very well and 37.3% never reported that they manage very well.

E.29 Tables EL6a–EL6c look at another measure of well-being and resources. In wave 2 onwards, respondents were asked whether having too little money stops them from doing any of the following things: buying your first choice of food items, having your family and friends round for a drink or meal, having an outfit to wear for social or family occasions, keeping your home in a reasonable state of decoration, replacing or repairing broken electrical goods, paying for fares or other transport costs to get to or from places you want to go, buying presents for friends or family once a year, taking the sorts of holidays you want, and treating yourself from time to time. An

index of material deprivation can be created by counting the number of items that a respondent reports that they cannot afford.

E.30 The question is asked once per individual, which means that even if members of a couple have access to the same financial resources, they can be recorded as feeling differently about whether they have too little money. For this reason, we split couples into ‘partnered men’ and ‘partnered women’, so any potential differences between men and women can be seen.

E.31 Tables EL6a–EL6c look at the persistence of reporting having too little money to do three or more items on the list described above. The numbers show the percentage of men or women who never report three or more items on the list (in waves 2–6), the percentage who report three or more items on the list in some waves (at least one wave but not all of waves 2–6) and the percentage who report three or more items on the list in every wave (2–6). Table EL6a looks at the percentages by education for single men, single women, partnered men and partnered women aged 50 to state pension age at baseline. Table EL6b is similar but shows the percentages for those aged from state pension age to 74 and Table EL6c shows the percentages for those aged 75 or over.

### **Labour market participation**

E.32 Tables EL7a and EL7b look at labour market participation by wealth group and age for men and women respectively. The first column of numbers reports the percentage of the whole baseline (wave 1) sample aged 50–74 who are employed (or self-employed) full- or part-time. The next five columns take the sample of individuals employed at baseline and report the percentage of those individuals who are employed in wave 1, wave 2, through to wave 6. By definition, 100% of the samples are employed in wave 1, but as we move further through time the percentage employed in each of the subsequent waves falls.

E.33 Table EL8 also looks at labour market participation but it considers transitions back into the labour market. The first column of figures reports the percentage of individuals who are not in employment at baseline (2002–03). The next five columns take the sample of people out of employment at baseline and report the percentage in employment at subsequent waves (by definition, 0% are employed in wave 1).

E.34 Tables EL9a and EL9b look at the persistency of health limiting an individual’s ability to work by wealth group and age. Respondents are asked whether they have a health problem that limits the kind or amount of work that they can do. As well as looking at the percentages of men (Table EL9a) and women (Table EL9b) who never report a limiting health problem and the percentage who always report a limiting health problem in waves 1–6, the tables also split those who sometimes report a limiting health problem into two distinct groups. The first is a ‘transitory’ group, for which we define a transitory limiting health problem as one that comes and goes throughout the six-wave period (a period spanning 12 years). For example, if an individual reported that they had a limiting health problem in waves 1, 3 and 6, we would define that as transitory. We define a limiting health problem as ‘onset’ if an individual starts the five-wave period without a limiting health problem but then reports a limiting health problem at some point during the period and reports it in all subsequent waves. For instance, an individual who reported a limiting health problem only in waves 4, 5 and 6 would be classed as having an ‘onset’ limiting health problem.

E.35 For example, Table EL9a shows that 64.2% of men aged 50–74 never had a limiting health problem in waves 1–6 and only 1.4% had a limiting health problem in every wave (1–6). The second column of numbers shows that 25.5% of men aged 50–74 sometimes had a limiting health problem that came and went over the six-wave period. The next column shows that 9.0% of men aged 50–74 sometimes had a limiting health problem but, unlike the group whose problem came and went, this group experienced the onset of the limiting health problem sometime in the five-wave period and it was not observed to go away.

## **Annex AE. Definitions**

AE.1 *Asset income*: Net income from any financial savings or investments (current and deposit accounts, TESSAs, ISAs, premium bonds, National Savings, PEPs, shares, trusts, bonds, other savings income not covered elsewhere) and any rental income from property (second homes, farm or business property) expressed in January 2013 prices.

AE.2 *Balanced panel*: The set of individuals who are interviewed in all waves of interest.

AE.3 *Baseline*: The wave of data that is chosen to be the starting point for characteristics in longitudinal analysis that may change over time.

AE.4 *Earnings*: The sum of employment income and self-employment income.

AE.5 *Education*: Low education is defined as leaving full-time education at or before compulsory school-leaving age. Medium education is defined as leaving full-time education after compulsory school-leaving age and before age 19. High education is defined as leaving full-time education at age 19 or above.

AE.6 *Employment income*: Net income from main and subsidiary jobs expressed in January 2013 prices.

AE.7 *Equivalisation*: Equivalising is a way of adjusting household resources to take account of different household sizes and the economies of scale involved in living with additional people in a household. An equivalence scale estimates how much expenditure or income different household types need to be equivalently well off and enables comparisons to be made across different family or household types. The equivalence scale used is the OECD scale, in which a single person with no children is taken as the benchmark. Secondary adults contribute 0.5 to the scale, meaning that a couple needs 50% more income than a single person in order to be assessed as equally well off. Children aged 13 and under contribute 0.3 to the scale and older children contribute 0.5. To convert the numbers to the equivalent amount that a childless couple spends, numbers should be multiplied by 1.5. Income is equivalised using a family-level equivalence scale and expenditure is equivalised using a household-level equivalence scale. Wealth is not equivalised. This is because there is no single accepted way to equivalise wealth. It is also not clear that it is sensible to equivalise wealth because the point at which wealth is used to fund consumption is likely to be in the future, when family composition may have changed from the current situation.

AE.8 *Expectations questions methodology*: ELSA includes a number of questions that ask respondents about their expectations of future events. Respondents are asked to report the chances from 0 to 100 that an event will happen in the future, where a higher number indicates a higher chance.

AE.9 *Family*: A couple or a single person and any children aged under 18 they may have who are living at home.

AE.10 *Income group*: To form income groups, we order all ELSA sample members according to the value of their total equivalised family income and divide the sample into five equal-sized groups. Where analysis is carried out using all ELSA sample members, the groups are equal in size and can be referred to as quintiles. Much of the analysis in this chapter is carried out using subsamples of the ELSA population. Where analysis does not use the whole ELSA sample, the groups are unequal in size

and are more accurately referred to as ‘income groups’. For consistency reasons, we use the term ‘income group’ rather than ‘income quintile’ throughout the chapter. The cut-off points for the income groups are shown in the following table, reported in January 2013 prices and rounded to the nearest £10:

	Income group definition, wave 1 (2002–03)	Income group definition, wave 6 (2012–13)
	<i>£ per week equivalised</i>	
Lowest	Less than £170	Less than £190
2 <sup>nd</sup>	Between £170 and £240	Between £190 and £270
3 <sup>rd</sup>	Between £240 and £320	Between £270 and £360
4 <sup>th</sup>	Between £320 and £460	Between £360 and £510
Highest	More than £460	More than £510

AE.11 *Net financial wealth*: Reported at the family level and defined as savings (interest-bearing current and deposit accounts, cash ISAs, TESSAs) plus investments (premium bonds, National Savings, PEPs, shares, trusts, bonds, the saving element of life insurance, shares ISAs and life insurance ISAs), but not including pensions or housing, minus debt (outstanding balances on credit cards, loans, mail-order and other private debt but not including mortgages). Expressed in January 2013 prices.

AE.12 *Net housing wealth*: Reported at the family level and defined as the self-reported current value of primary housing (i.e. residential housing) less any debt outstanding on that house. Expressed in January 2013 prices.

AE.13 *Net physical wealth*: Reported at the family level and defined as wealth held in second homes, farm or business property, other business wealth, other land and other assets such as jewellery or works of art or antiques. Expressed in January 2013 prices.

AE.14 *Other income*: Net income coming from individuals outside the household such as maintenance payments. Expressed in January 2013 prices.

AE.15 *Private pension income*: Net income from private pensions and annuities (from all non-state sources). Expressed in January 2013 prices.

AE.16 *Self-employment income*: Net income from self-employment. This is defined as profit (converted to a weekly equivalent) for self-employed individuals who keep accounts or income from self-employment for those who do not keep accounts. Self-employment income can be negative if those keeping accounts make a loss. Expressed in January 2013 prices.

AE.17 *State benefit income*: Income from the following state benefits: incapacity benefit, employment and support allowance (wave 5 onwards), severe disablement allowance, statutory sick pay, attendance allowance, disability living allowance, industrial injuries allowance, war pensions, invalid care allowance (wave 1), carer’s allowance (wave 2 onwards), disabled person’s tax credit (wave 1), income support, pension credit (wave 2 onwards), working families’ tax credit (wave 1), working tax credit (wave 2 onwards), jobseeker’s allowance, guardian’s allowance, widow’s pension, child benefit and child tax credit (wave 2 onwards). State benefit income does not include housing benefit or council tax benefit. Expressed in January 2013 prices.

AE.18 *State pension age (SPA)*: Various changes to the SPA have been phased in and further changes have been announced or planned. Women born on or after 6 April 1950 in our sample are affected by a gradual increase in the SPA between April 2010

and November 2018. Calculation of state pension age in this report incorporates these changes. This means that women’s SPA varies according to date of birth. For the tables in this report, women aged up to 61 can be below SPA. Men currently in our sample are not currently affected by the changes and their SPA remains at 65. Further details can be found at <https://www.gov.uk/changes-state-pension>.

**AE.19 State pension income:** Net income from state pensions (basic state pension, State Earnings-Related Pension Scheme / state second pension). Expressed in January 2013 prices.

**AE.20 Total (family) income:** Total income is defined net of taxes and is the sum of employment income (including income from self-employment), private pension income, state pension income, other state benefit income (excluding housing benefit and council tax benefit), asset income and any other income. Total income is summed across family members (where a family is defined as a couple or a single person and any children aged under 18 they may have who are living at home) to obtain family income. Expressed in January 2013 prices.

**AE.21 Total non-pension wealth:** Reported at the family level and defined as the sum of net financial wealth, net physical wealth and net housing wealth. Expressed in January 2013 prices.

**AE.22 Wealth group:** To form wealth groups, we order all ELSA sample members according to the value of their total (non-pension) family wealth and divide the sample into five equal-sized groups. Where analysis is carried out using all ELSA sample members, the groups are equal in size and can be referred to as quintiles. Much of the analysis in this chapter is carried out using subsamples of the ELSA population. Where analysis does not use the whole ELSA sample, the groups are unequal in size and are more accurately referred to as ‘wealth groups’. For consistency reasons, we use the term ‘wealth group’ rather than ‘wealth quintile’ throughout the chapter. The cut-off points for the wealth groups are shown in the following table, reported in January 2013 prices and rounded to the nearest £1,000:

	<b>Wealth group definition, wave 1 (2002–03)</b>	<b>Wealth group definition, wave 6 (2012–13)</b>
Lowest	Less than £19k	Less than £48k
2 <sup>nd</sup>	Between £19k and £130k	Between £48k and £170k
3 <sup>rd</sup>	Between £130k and £226k	Between £170k and £273k
4 <sup>th</sup>	Between £226k and £400k	Between £273k and £450k
Highest	More than £400k	More than £450k

### **AE.23 Notes to all tables**

The unit of observation in all tables is the individual.

All cross-sectional tables are based on the cross-section of ELSA sample members in wave 6 of the data. This includes refreshment sample members.

All longitudinal tables are based on individuals who have responded in all of waves 1 to 6 (the ‘balanced panel’) unless otherwise specified.

All numbers are based on weighted data. Both unweighted and weighted frequencies (N) are reported.

For cross-sectional analyses, cross-sectional weights are used. For longitudinal analyses, longitudinal weights are used.

Values are converted to January 2013 prices using the retail price index (RPI).

The fieldwork dates are shown in the following table:

The fieldwork timetable is as follows:

	<b>Fieldwork dates (inclusive)</b>
Wave 1	March 2002 – March 2003
Wave 2	June 2004 – June 2005
Wave 3	May 2006 – August 2007
Wave 4	June 2008 – July 2009
Wave 5	July 2010 – June 2011
Wave 6	May 2012 – May 2013

80+	[100.0]	[0.0]	[0.0]	[4.6]	[79.2]	[16.2]	47	37

Note: The response categories are 'manage very well', 'manage quite well', 'get by alright', 'don't manage very well', 'have some financial difficulties' and 'have severe financial difficulties'. For the purposes of this table, 'having financial difficulties' includes those reporting that they 'don't manage very well', 'have some financial difficulties' or 'have severe financial difficulties'. Those 'managing very well' for the purposes of this table include only those reporting in the highest category (manage very well).

For variable definitions, see AE.23. For related text, see E.27 and E.28.

# S. Social domain tables

**Katey Matthews** *University of Manchester*

**James Nazroo** *University of Manchester*

## Introduction

S.1 This chapter presents selected data tables from the Social domain of the English Longitudinal Study of Ageing. The tables are split into two sections:

- Cross-sectional tables (Tables S1–S14) involve classification by sex and age (divided into five-year categories) and classification by sex and wealth group. Tables S1–S14 contain data for all core members at wave 6 (2012–13), including people from the original ELSA cohort in 2002–03 and the refreshment sample members added to ELSA in 2006–07 (wave 3), 2008–09 (wave 4) and 2012–13 (wave 6). These cross-sectional tables show a representative sample of people aged 50 and over in 2012–13.
- Longitudinal tables (Tables SL1–SL7) include a balanced ELSA sample who participated in all of waves 1 to 6. Again, classifications by sex and age and by sex and wealth group are presented. The longitudinal tables show the change over time in a representative sample of people aged 50 and over in 2002–03. For example, Table SL4a shows the percentage of people using public transport in wave 1 and the percentage still using public transport in every wave up to and including wave 6 (2012–13). Differences across the waves can be interpreted as a consequence of a combination of ageing and period effects.

S.2 The unit of observation in all tables is the individual. The data are weighted using either a cross-sectional (main questionnaire or self-completion questionnaire) or longitudinal weight as appropriate. The variables included in each table have been selected to provide a broad picture of the data available from the Social domain of ELSA. A glossary of the measures is provided in the annex to this chapter.

## Cross-sectional tables

### Socio-demographic

S.3 Table S1a shows the percentage of men and women by marital status and age in 2012–13. The majority of men and women are reportedly married or have remarried. The percentage of women who reported being married or remarried declines with age from 62% in those aged 50–54 to 26% in those aged 80 and above. The percentage of men and women reporting as widowed rises considerably with age, particularly for women. Almost two-thirds of women aged 80 and above are widowed (63%) compared with almost a third of men aged 80 and above (32%). There is a decline in the percentage of men who remained single as they aged, with 2% of men aged 80 or above reporting being single. This is compared with a U-shaped relationship with age for women. The decline with age in the percentage who reported being divorced or separated is similar for men and women.

S.4 Table S1b shows the percentage of men and women by marital status and wealth in 2012–13. The percentage of men and women married or remarried in the three highest wealth groups is as much as double that of the lowest wealth group. Men and women in the lowest wealth group are much more likely to be single, divorced or separated, or widowed than those in higher wealth groups. This is partially explained by the family-level wealth measure used in the analysis (see Table E3 in Economics domain tables, Chapter E).

S.5 Table S2a shows the percentage of men and women by ethnicity and age in 2012–13. Across each age group, the vast majority of men (94%) and women (95%) identify as white. However, the percentage of white respondents increases with age for men and women. Table S2b shows the percentage of men and women by ethnicity and wealth group in 2012–13. Of those men and women who self-identified as non-white, a slightly higher proportion were in the lowest wealth group than in the highest wealth group.

### **Internet and recreation**

S.6 Table S3a shows the percentage of men and women by usage of the internet and age in 2012–13. Nearly three-quarters of men (74%) and over six in ten of women (64%) report that they use the internet. However, usage of the internet declines with age, particularly for women. Among those aged 80 and above, 15% of the women report using the internet compared with 36% of the men.

S.7 Table S3b shows the percentage of men and women by usage of the internet and wealth in 2012–13. There is a strong wealth gradient in internet usage among men and women. Just over half of men in the lowest wealth group report using the internet (52%), compared with almost nine-tenths of those in the highest wealth group (89%). These figures are 44% and 83%, respectively, for women.

S.8 Table S4a shows the mean weekly hours of TV watched, by sex and age in 2012–13. On average, men view 15 hours of TV per week and women view 16 hours. The number of hours of TV viewed per week is similar across age groups for men and women. Table S4b shows the mean weekly hours of TV watched by sex and wealth. It suggests that men and women in higher wealth groups watch less TV, on average, than those in lower wealth groups.

S.9 Table S5a shows the percentage of men and women who have taken a holiday, in the UK or abroad, in the last year by age in 2012–13. Around three-quarters of men and women aged between 50 and 74 have taken a holiday in the last year. The percentage is lower for men and women from age 75 onwards, and by age 80 less than half of men and women (47% and 43%, respectively) have taken a holiday in the last year.

S.10 Table S5b shows the percentage of men and women who have taken a holiday, in the UK or abroad, in the last year by wealth in 2012–13. The proportion of men and women in the highest wealth group taking a holiday is about double that for those in the lowest wealth group. Nonetheless, almost half of men and women in the lowest wealth group reported having been on holiday in the last year.

### **Transport and services**

S.11 Table S6a shows the percentage of men and women by the frequency of public transport use and age in 2012–13. Women report using public transport more often than men, but this difference is marginal. The frequency of public transport usage

tends to increase for older individuals up to the age of 80. Public transport usage declines rapidly for men and women over the age of 80, with almost half of men and women never using public transport by age 80.

S.12 Table S6b shows the percentage of men and women by the frequency of public transport use and wealth in 2012–13. Men and women in lower wealth groups are more likely to report using public transport regularly (i.e. at least once a week) than those in higher wealth groups, but those in lower wealth groups are also more likely to report never using public transport than those in higher wealth groups.

S.13 Table S7a shows the percentage of men and women who have access to a car or van when needed, by age in 2012–13. Of those who do, the table shows the percentage who drive this vehicle themselves; and of those who do not, the table shows the percentage who drove a vehicle in the past. The percentage of those reporting access to a car or van remains reasonably stable across age groups, but those aged 75 and over see a sharp decline in access. Just over half of women aged 80 and over (52%) have access to a vehicle when needed, compared with three-quarters of men (76%). The majority of men of all ages drive this vehicle themselves, but among women the percentage driving themselves declines with age at a greater rate. Over four-fifths of men aged 80 and over (83%) drive their own vehicle, compared with less than half of women aged 80 and over (47%). The percentage of non-drivers in 2012–13 who drove in the past increases with age at a greater rate for men than for women. Over four-fifths of non-driving men aged 80 and over (83%) drove in the past, compared with less than two-fifths of women aged 80 and over (39%).

S.14 Table S7b shows the percentage of men and women who have access to a car or van when needed, by wealth in 2012–13. Of those who do, the table shows the percentage who drive this vehicle themselves; of those who do not, the table shows the percentage who drove a vehicle in the past. Almost all men and women in the highest wealth quintile have access to a vehicle when needed, compared with just over three-fifths of men (63%) and just over half of women (57%) in the lowest wealth group. There is a 10 percentage point reduction in the proportion of men driving vehicles themselves in the lowest wealth group compared with the highest, but among women this difference is over 40 percentage points. Among non-drivers, rates of having driven in the past are higher among higher wealth groups.

S.15 Table S8a shows the percentages of men and women who find it difficult to get to a bank, post office, corner shop, supermarket, shopping centre, GP, chiropodist, dentist, optician and hospital, by age in 2012–13. Hospitals and shopping centres are the places that both men and women find it most difficult to get to. Older individuals, particularly women, find it more difficult to get to places than younger individuals. Over a third of women and around a quarter of men aged 80 and over find it difficult to get to a hospital (35% and 24%, respectively) or a shopping centre (36% and 25%, respectively).

S.16 Table S8b shows the percentages of men and women who find it difficult to get to a bank, post office, corner shop, supermarket, shopping centre, GP, chiropodist, dentist, optician and hospital, by wealth in 2012–13. Men and women in lower wealth groups find it more difficult to get to these places than those in higher wealth groups. Around a fifth of men and a quarter of women in the lowest wealth group find it difficult to get to a hospital (23% and 25%, respectively) or a shopping centre (21% and 25%, respectively), while less than a tenth of those in the highest wealth group

have difficulty in getting to a hospital (9% of both men and women) or a shopping centre (7% of both men and women).

### **Providing social support**

S.17 Table S9a shows the percentage of men and women by frequency of voluntary work and age in 2012–13. The prevalence of frequent voluntary work (i.e. twice a month or more) among men and women is greater as they age up to 75. Around a fifth of men and a quarter of women aged 70–74 (19% and 25%, respectively) do voluntary work at least twice a month. In later age, the prevalence of volunteering declines for men and women, particularly in those aged 80 and over.

S.18 Table S9b shows the percentage of men and women by the frequency of voluntary work and wealth in 2012–13. Men and women in higher wealth groups are more likely to volunteer and volunteer more often than those in lower wealth groups. At least two-fifths of men and women in the highest wealth group (41% for both men and women) did some voluntary work in the last year compared with one-in-seven of those in the lowest wealth group.

S.19 Table S10a shows the percentage of men and women who cared for someone in the last month by age in 2012–13. The prevalence of caring for someone in the last month is 8% among men and 16% among women. The percentage of men who cared for someone in the last month is fairly stable across age groups. However, the percentage of women who cared for someone declines considerably with age, from 22% for those aged 60–64 to 4% for those aged 80 and over.

S.20 Table S10b shows the percentage of men and women who cared for someone in the last month by wealth in 2012–13. The percentage who cared for someone in the last month is similar across wealth groups for men but increases with wealth group for women.

### **Receipt of social support**

S.21 Table S11a shows the percentage of men and women with an ADL or IADL difficulty (see AS.9 for details of definitions) who receive help (including from their partner or other people in the household) by age in 2012–13. Almost a third of men (33%) and over two-fifths of women (42%) with a difficulty receive help. The proportion increases with age in men and women. More than half of men aged 80 and over (55%) and over two-thirds of women aged 80 and over (71%) with a difficulty receive help.

S.22 Table S11b shows the percentage of men and women with an ADL or IADL difficulty who receive help (including from their partner or other people in the household) by wealth in 2012–13. The proportion of men and women with a difficulty receiving help is lower for those in higher wealth groups. Over a quarter of men and women in the highest wealth group (27% and 30%, respectively) with a difficulty receive help, compared with over two-fifths of men (45%) and over half of women (57%) in the lowest wealth group.

S.23 Table S12a shows the mean number of close relationships with children, family and friends for men and women by age in 2012–13. On average, men and women have seven or eight close relationships. This varies marginally by age.

S.24 Table S12b shows the mean number of close relationships with children, family and friends for men and women by wealth in 2012–13. On average, men and

women in the higher wealth groups have marginally more closer contacts than those in the lower wealth groups.

### **Perceived social status**

S.25 Table S13a shows the percentage of men and women by self-perceived social status and age in 2012–13. More than three-quarters of men and women perceive their social position to be on the third, fourth or fifth rung of a five-point social ladder, where the fifth rung is the best-off and the first rung is the worst-off. Around two-fifths of men aged 50–74 rank their social position as being in the highest two rungs of society (best-off and fourth rungs), but this drops to around a third thereafter. Over a third of women aged 60–64 rank their social position as being in the highest two rungs of society; this percentage then decreases with age.

S.26 Table S13b shows the percentage of men and women by self-perceived social status and wealth in 2012–13. Men and women in the lower wealth groups are more likely to rank their status lower on the social ladder than those in the higher wealth groups.

### **Expectation of life expectancy**

S.27 Table S14a shows the mean self-perceived chance of living to 85 for men and women aged below 70 by age in 2012–13. Women are more optimistic about their chances of living to 85 than men. The average man believes that there is a 48% chance he will live to 85, compared with the average woman believing she has a 53% chance of doing so. The percentage of women who expect to live to age 85 increases steadily with age. For men, the percentage increases from age 55 onwards, after an initial drop of 4 percentage points between the ages of 50–54 and 55–59.

S.28 Table S14b shows the mean self-perceived chance of living to 85 for men and women aged below 70 by wealth in 2012–13. Men and women in the highest wealth group are, on average, 10 percentage points more likely to expect to live to 85 than those in the lowest wealth group. Nonetheless, women in the lowest wealth group, on average, believe they have a 47% chance of living to 85 and men in the lowest wealth group, on average, believe they have a 42% chance of living to 85.

## **Longitudinal tables**

### **Marital status**

S.29 Table SL1a shows the percentage of men and women married or remarried at baseline (wave 1) and the percentage still married across each wave, by age. The majority of married men and women in 2002–03 remained in a marriage by 2012–13. However, this varies by age, particularly for women. For example, less than half (46%) of married women aged 75 and over at baseline were still married by wave 6. Over two-thirds (70%) of men aged 75 and over were still married by wave 6. Almost all no-longer married men and women became widowed in a later wave of ELSA rather than separated or divorced.

S.30 Table SL1b shows the percentage of men and women married or remarried at baseline (wave 1) and the percentage still married across each wave, by wealth. Men and women married in 2002–03 in the lowest wealth group are less likely to remain in a marriage by 2012–13 than those in higher wealth groups.

## **Internet**

S.31 Table SL2a shows the percentage of men and women using the internet at baseline (wave 1) and the percentage still using it in subsequent waves, by age. The majority of men and women using the internet in 2002–03 continued to use the internet by 2012–13.

S.32 Table SL2b shows the percentage of men and women using the internet at baseline (wave 1) and the percentage still using it in subsequent waves, by wealth. Men and women in the highest wealth group are much more likely to continue using the internet across each wave of ELSA than those in the lowest wealth group. This is most apparent for women in the lowest wealth group, of whom around a third (30%) who reported using the internet at baseline in 2002–03 stated they did not use it by wave 6 (2012–13).

S.33 Table SL2c shows the percentage of men and women not using the internet at baseline and, of those, the percentage using it in subsequent waves, by age. Around two-thirds of men and women aged 50–54 (67% and 63%, respectively) and over half of men and women aged 55–59 (52% and 54%, respectively) who were not using the internet in 2002–03 stated that they were using it by 2012–13. The proportion of men and women starting to use the internet is lower for each older age group, and women aged 65 and over are considerably less likely to start using the internet than men of the same age.

S.34 Table SL2d shows the percentage of men and women not using the internet at baseline and, of those, the percentage using it in subsequent waves, by wealth. Men and women in the highest wealth group are consistently at least twice as likely to start using the internet as those in the lowest wealth group. Furthermore, half of men (50%) in the highest wealth group not using the internet in 2002–03 did start using it by wave 4 (2008–09). Among women in the highest wealth group not using the internet at baseline, more than half (54%) had started to use it by 2012–13.

## **Holidays**

S.35 Table SL3a shows the percentage of men and women having been on holiday in the last year at baseline (wave 1) and the percentage still having been on holiday in the last year in subsequent waves, by age. In each wave up to and including wave 6, at least four-fifths of men and women having been on holiday at baseline (2002–03) had also been on holiday in the last year (83% of men and 80% of women had been on holiday in 2012–13). The proportion of men and women continuing to go on holiday in subsequent waves is lower for older individuals. Only slightly over half of men aged 75 and over (55%) and slightly less than half of women aged 75 and over (49%) reported having been on holiday at wave 6 (2012–13), after reporting that they had been on holiday in 2002–03.

S.36 Table SL3b shows the percentage of men and women having been on holiday in the last year at baseline (wave 1) and the percentage still having been on holiday in the last year in subsequent waves, by wealth. Men and women in the lowest wealth group are more likely to report not going on holiday in subsequent waves. By 2012–13, around two-fifths of women (44%) and more than a third of men (38%) in the lowest wealth group reported not going on holiday in the last year, having reported that they did at baseline. This compares with just over a tenth of those in the highest wealth group.

## **Transport**

S.37 Table SL4a shows the percentage of men and women who used public transport at baseline (wave 1) and the percentage still using public transport in subsequent waves, by age. The majority of men and women still used public transport in 2012–13 having already been using public transport in 2002–03. The proportion is lower for those aged 75 and over for men and women, of whom only around half still used public transport in 2012–13 (50% and 52%, respectively). The proportion still using public transport increased after wave 3 (2006–07). This coincides with the introduction of free off-peak bus travel for over-60s in April 2008. The increase was greatest for men aged 55–64 and women aged 55–59.

S.38 Table SL4b shows the percentage of men and women who used public transport at baseline (wave 1) and the percentage still using public transport in subsequent waves, by wealth. The majority of men and women in each wealth group still used public transport in subsequent waves of ELSA.

S.39 Table SL4c shows the percentage of men and women who did not use public transport at baseline (wave 1) and, of those, the percentage using public transport in subsequent waves, by age. Men aged 55–69 and women aged 50–69 in 2002–03 are more likely to start using public transport than those in other age groups. The proportion of men and women in all age groups starting to use public transport increased after wave 3 (2006–07). This coincides with the introduction of free off-peak bus travel for over-60s in April 2008.

S.40 Table SL4d shows the percentage of men and women who did not use public transport at baseline (wave 1) and, of those, the percentage using public transport in subsequent waves, by wealth. Men and women in the lowest wealth group are less likely to start using public transport than those in higher wealth groups. Over two-fifths of men and women (both 43%) in the highest wealth group not using public transport in 2002–03 started using public transport by 2012–13.

S.41 Table SL5a shows the percentage of men and women with access to a car or van when needed at baseline (wave 1) and, of those, the percentage with a car or van when needed in subsequent waves, by age. For men only, those at older ages (70 and above) see a decline in car access over time. For women, this decline appears to happen among younger cohorts (from age 60 onwards), and the decline is more rapid. By 2012–13, only just over half of women (55%) aged 75 and over who had access to a car at baseline still had access to a car when needed. This compares with 71% of men in the same age group.

S.42 Table SL5b shows the percentage of men and women with access to a car or van when needed at baseline (wave 1) and, of those, the percentage with a car or van when needed in subsequent waves, by age. There is a general decline in car access over time across all wealth groups, but the decline is greater in the lower wealth quintiles and again occurs more rapidly among women. By 2012–13, 89% of men in the lowest wealth group who had access to a car at baseline still had access when needed, compared with 66% of women in that wealth group.

## **Volunteering**

S.43 Table SL6a shows the percentage of men and women volunteering at baseline (wave 1) and the percentage still volunteering in subsequent waves, by age. Men and women aged 50–59 are less likely to continue volunteering than those aged 60–64.

Over four-fifths of men aged 75 and over (81%) and three-quarters of women aged 75 and over (75%) who volunteered in 2002–03 did not volunteer by 2012–13.

S.44 Table SL6b shows the percentage of men and women volunteering at baseline (wave 1) and the percentage still volunteering in subsequent waves, by wealth. Men and women in the higher wealth groups are more likely to continue volunteering across each wave of ELSA. A quarter of men in the lowest wealth group (25%) still volunteered by 2012–13, compared with almost two-thirds of those in the highest wealth group (61%).

S.45 Table SL6c shows the percentage of men and women not volunteering at baseline (wave 1) and, of those, the percentage volunteering in subsequent waves, by age. The vast majority of men and women not volunteering in 2002–03 did not start volunteering by 2012–13. Men and women aged under 70 are more likely to have started volunteering than those aged 70 and above.

S.46 Table SL6d shows the percentage of men and women not volunteering at baseline (wave 1) and, of those, the percentage volunteering in subsequent waves, by wealth. Men and women in the highest wealth group are more likely to have started volunteering than those in lower wealth groups. About a quarter of men (26%) and almost a fifth of women (19%) in the highest wealth group not volunteering in 2002–03 had started to volunteer by 2012–13.

## **Caring**

S.47 Table SL7a shows the percentage of men and women who did not care for someone in the last month at baseline (wave 1) and, of those, the percentage caring for someone in the last month in subsequent waves, by age. The vast majority of men and women in each age group did not start caring for someone by 2012–13. However, men aged 60–64 and women aged under 65 are more likely to have started caring for someone than those at other ages.

S.48 Table SL7b shows the percentage of men and women who did not care for someone in the last month at baseline (wave 1) and, of those, the percentage caring for someone in the last month in subsequent waves, by wealth. The vast majority of men and women did not start caring for someone by 2012–13. However, women in the lowest wealth group are less likely to have started caring for someone than those in higher wealth groups, particularly those in the two highest wealth groups.

## Annex AS. Definitions

AS.1 *Age* is defined as age at last birthday.

AS.2 *Baseline* is defined as wave 1 of ELSA. Fieldwork for wave 1 was conducted in 2002 and 2003. Subsequent waves have been conducted every two years, with the most recent (wave 6) conducted in 2012 and 2013.

AS.3 *Caring* is defined as whether a respondent cared for someone in the last month.

AS.4 *Close relationships* are defined as the number of close relationships a respondent has with their children, family and friends.

AS.5 *Ethnicity* is measured by a dichotomous categorisation of white and non-white. The ELSA sample is known not to be representative of the ethnic minority population aged 50 and over in England.

AS.6 *Holidays taken in the last year* are measured by whether a respondent has taken a holiday, in the UK or abroad, in the last 12 months.

AS.7 *Internet usage* is defined by whether a respondent uses the internet and/or email. Those classed as not using the internet report using it less than once every three months or never.

AS.8 *Marital status* is defined as per a respondent's legal status.

AS.9 *Mobility assistance* is defined as whether a respondent with an ADL or IADL difficulty receives assistance with these activities, including from a partner or other people in the household. Activities of daily living (ADLs) include dressing, getting around inside the home, bathing or showering, eating, getting in or out of bed and using the toilet. Instrumental activities of daily living (IADLs) include preparing a hot meal, shopping, making telephone calls, taking medication, doing household chores and managing personal finances.

AS.10 *Private transport usage* is measured by whether a respondent has access to a car or van when needed.

AS.11 *Public transport usage* is measured by frequency categories: every day or nearly every day; two or three times a week; once a week; two or three times a month; once a month or less; and never. At waves 1–2, the following usage categories were used: a lot; quite often; sometimes; rarely; and never.

AS.12 *Self-perceived chance of living to 85* is measured by the mean of respondents' assessments of the probability (0 to 100) of them living to 85 for those aged 69 and below.

AS.13 *Self-perceived social status* is measured by respondents indicating on the rung of a ladder where they stand in society based on money, education and employment.

AS.14 *Service access* is measured by whether a respondent finds it 'quite' or 'very' difficult to get to or is 'unable to go to' a range of places using their usual form of transport.

AS.15 *Tenure* is defined as accommodation type with the following categories: own outright; own with mortgage or shared ownership; private renting or rent free; and social renting from local authority or housing association.

## *Social domain tables*

AS.16 *TV viewing* is defined as the mean number of hours of television watched during an ordinary week.

AS.17 *Volunteering* is defined by frequency of any voluntary work carried out: twice a month or more; about once a month; every few months; about once or twice a year; less than once a year; and never.

AS.18 *Wealth* is defined as non-pension wealth minus any debt. Net non-pension wealth is measured at the family level and includes financial wealth from savings and investments minus debts, physical wealth (wealth held in second homes, farm or business property, other business wealth, other land and other assets such as jewellery or works of art or antiques) minus debts, and housing wealth minus mortgages.

AS.19 *Wealth groups* are formed by ordering all ELSA sample members according to the value of their total (non-pension) family wealth and dividing the sample into five equal-sized groups. The cut-off points for the wealth groups are shown in the following table, reported in January 2013 prices and rounded to the nearest £1,000:

	<b>Wealth group definition, wave 1 (2002–03)</b>	<b>Wealth group definition, wave 6 (2012–13)</b>
Lowest	Less than £19k	Less than £48k
2 <sup>nd</sup>	Between £19k and £130k	Between £48k and £170k
3 <sup>rd</sup>	Between £130k and £226k	Between £170k and £273k
4 <sup>th</sup>	Between £226k and £400k	Between £273k and £450k
Highest	More than £400k	More than £450k

### **AS.20 Notes to all tables**

The unit of observation in all tables is the individual.

All cross-sectional tables are based on the cross-section of ELSA sample members in wave 6 of data. This includes refreshment sample members.

All longitudinal tables are based on individuals who have responded in all of waves 1 to 6 (the ‘balanced panel’) unless otherwise specified.

All numbers are based on weighted data. Unweighted frequencies (N) are reported.

For cross-sectional analyses, cross-sectional weights are used. For longitudinal analyses, longitudinal weights are used.

The fieldwork dates are shown in the following table:

	<b>Fieldwork dates (inclusive)</b>
Wave 1	March 2002 – March 2003
Wave 2	June 2004 – June 2005
Wave 3	May 2006 – August 2007
Wave 4	June 2008 – July 2009
Wave 5	July 2010 – June 2011
Wave 6	May 2012 – May 2013

**Table S1a. Marital status (%), by age and sex: wave 6**

	Age in 2012–13							All

# H. Health domain tables

Aparna Shankar *University College London*

Cesar de Oliveira *University College London*

## Introduction

H.1 This chapter presents results for the Health domain of the latest wave of the English Longitudinal Study of Ageing. The tables cover self-reported health, diagnosed chronic health conditions, walking speed, limitations with activities of daily living and instrumental activities of daily living, cognitive function, health behaviours and quality of life. As this wave also included a nurse visit, we include tables on anthropometric measures, physical function tests and biomarkers. In addition to cross-sectional tables relating to core sample members at this wave, we also have longitudinal tables showing changes in these variables over time for core sample members who have been in the study since wave 1. Annex AH provides information on the measures used for each table. Details regarding the samples for these tables are as follows:

- Health status cross-sectional tables (H1 to H9): These results are for core sample members at wave 6 and include refreshment samples from waves 3, 4 and the current wave (6). The analyses are weighted using cross-sectional weights, which adjust for non-response. Results are shown by age category (five-year age bands) and sex or by wealth group and sex.
- Health status longitudinal tables (HL1 to HL11): These results are for the *balanced panel* of participants who were present at every wave from wave 1 to wave 6, and are weighted using longitudinal weights. As above, results are presented by age category (five-year age bands using age at wave 1) and sex or by wealth group (at wave 1) and sex.
- Nurse visit cross-sectional tables (N1 to N11): These results include core sample members from the main interview who then consented to the nurse visit. Results are shown by age category and sex or by wealth group and sex. Anthropometric and physical functioning measures are weighted by nurse visit weights, while blood sampling results are weighted by blood sampling weights.
- Nurse visit longitudinal tables (NL1 to NL17): These results include those participants who provided data at all three nurse visits (waves 2, 4 and 6). Again the results are presented by age category (five-year age bands using age at wave 2) and sex or by wealth group (at wave 2) and sex. These results are unweighted.

## Health status cross-sectional tables

### General health

H.2 Table H1a shows self-rated health by age category and sex. In general, poor self-rated health increases with age. Patterns of reporting are similar for men and women, and just over a quarter of participants reported fair or poor self-rated health.

H.3 Table H1b shows self-rated health by wealth group and sex. A clear wealth gradient is seen such that excellent self-rated health increases and poor self-rated health decreases with greater wealth.

H.4 Table H2a shows the percentage of individuals who report having a limiting long-standing illness by age category and sex. In general, limiting long-standing illness is more commonly reported by women. For both men and women, the proportion of individuals who report having a limiting long-standing illness increases with age.

H.5 Table H2b shows the percentage of individuals who report having a limiting long-standing illness by wealth group and sex. While over half of men and women in the poorest group report having a limiting long-standing illness, under a fifth of men and just over a quarter of women in the wealthiest group report having a limiting long-standing illness.

### **Diagnosed health conditions**

H.6 Table H3a shows the prevalence of six diagnosed health conditions (CHD, diabetes, cancer, respiratory disease, arthritis and depression) by age category and sex. For most health conditions, prevalence increases with age, but depression shows the opposite trend. While CHD and diabetes are more prevalent among men, cancer, arthritis and depression are more prevalent among women.

H.7 Table H3b shows the prevalence of the above diagnosed health conditions by wealth group and sex. The prevalence of these chronic conditions is generally higher among the lower wealth groups, with a clear gradient apparent for most conditions. Cancer is, however, an exception, with prevalence being higher among wealthier participants, particularly in women.

### **Disability**

H.8 Table H4a shows mean walking speed (m/s) by age category and sex. Walking speed declines rapidly with age and men have higher walking speeds at every age than women.

H.9 Table H4b shows mean walking speed by wealth group and sex. For men and women, mean walking speeds increase with wealth.

H.10 Table H5a shows the percentage of participants reporting limitations with one or more activities of daily living (ADLs) and with one or more instrumental activities of daily living (IADLs) by age category and sex. Within each age category, a higher proportion of women have difficulties with ADLs and IADLs. The prevalence of difficulties with ADLs and IADLs increases with age.

H.11 Table H5b shows the percentage of participants reporting difficulties with ADLs and IADLs by wealth group and sex. A wealth gradient is apparent, with the prevalence of limitations decreasing with increasing wealth. While a greater proportion of women report disabilities, the sex difference is most marked when considering IADLs.

### **Cognitive function**

H.12 Table H6a shows scores on the recall tests and the fluid intelligence test by age category and sex. Overall, both men and women show a decrease in cognitive function with age. Among men, scores on both measures are stable between the ages

of 50 and 64 and thereafter start to decline. Among women, scores remain relatively stable till the age of 70 and then decline. While recall scores are higher among women, scores on fluid intelligence are higher for men.

H.13 Table H6b shows scores on cognitive function tests by wealth group and sex. Scores on both tests show increases with wealth, such that recall was about 25% higher in the wealthiest group than in the poorest group and scores on the fluid intelligence score were nearly 5% higher.

### **Health behaviours**

H.14 Table H7a shows the percentage of participants who smoke currently, drink daily, report low physical activity and consume fewer than five portions of fruit and vegetables daily. The proportion of smokers decreases with age, while the prevalence of inactivity increases. Daily drinking is most common among those aged 65–69. Low fruit and vegetable consumption generally decreases with age for men but patterns are less clear for women. When compared with men, daily drinking and low fruit and vegetable consumption are less common among women but physical inactivity is more common.

H.15 Table H7b shows the percentage of participants reporting the above health risk behaviours by wealth group and sex. Smoking, inactivity and low fruit and vegetable consumption decrease with increasing wealth, while daily drinking shows the opposite pattern.

### **Quality of life and depressive symptoms**

H.16 Table H8a shows the mean scores on the CASP quality of life measure by age category and sex. For men, quality of life shows small increases up to age 69, following which there are decreases. Patterns are less clear for women. There are no appreciable gender differences in quality of life.

H.17 Table H8b shows the mean scores on the CASP measure by wealth group and sex. Quality of life is higher among wealthier participants.

H.18 Table H9a shows mean scores on the Center for Epidemiologic Studies depression (CESD) scale and the proportion of individuals classified as depressed when using this scale, by age category and sex. Mean scores do not show a clear pattern of change with age. The percentage of individuals classified as depressed decreases till age 75 for women, following which there is an increase. Mean scores and proportion depressed are higher among women.

H.19 Table H9b shows mean scores on the CESD scale and the proportion of individuals classified as depressed when using this scale, by wealth group and sex. Around 30% of participants in the lowest wealth group are classified as depressed, compared with 8.9% of women and 4.3% of men in the wealthiest group. This social gradient is also apparent in the mean scores.

## **Health status longitudinal tables**

### **General health**

H.20 Table HL1a shows the percentage of participants reporting fair or poor self-rated health from waves 1 to 6 by age category in wave 1 and sex.<sup>1</sup> For each baseline age category, there is an increase across waves in the proportion of participants reporting fair or poor self-rated health. This increase is most marked in the older age groups.

H.21 Table HL1b shows the percentage of participants reporting fair or poor self-rated health from waves 1 to 6 by wealth group in wave 1 and sex.<sup>2</sup> All groups show increases across waves in the proportion of participants reporting poor or fair self-rated health, though the increase is greatest among the poorest groups. At wave 6, the proportion of participants in the wealthiest group who report fair or poor health is smaller than the proportion of participants in the poorest group who report fair or poor health at baseline.

### **Diagnosed health conditions**

H.22 Tables HL2a, HL3a and HL4a show the prevalence of CHD, diabetes and depression from waves 1 to 6 by age category at wave 1 and sex. For all conditions, there is an increase in prevalence at each wave. It must be noted that the tables report the percentage of participants who ever report a condition (see AH.19) and in such a case the increase in every successive wave is to be expected. In the case of CHD and diabetes, increases are generally greater in older groups, while increases are greater among younger age groups for depression.

H.23 Tables HL2b, HL3b and HL4b show the prevalence of CHD, diabetes and depression from waves 1 to 6 by wealth group at wave 1 and sex. For each wealth group, there are increases in prevalence over time and these are most marked in the poorer groups. This indicates that socio-economic inequalities in diagnosed conditions have increased over the decade.

### **Disability**

H.24 Table HL5a shows the mean walking speed by baseline age category and sex. For all age groups, walking speed decreased with time, and decline was greatest for the older groups. Overall, walking speeds are lower for women than for men.

H.25 Table HL5b shows the mean walking speed by baseline wealth group and sex. There are decreases in walking speeds for all wealth groups, though poorer groups start with lower walking speeds and decrease faster. Indeed, the wave 6 mean walking speed for the wealthiest group is greater than the mean wave 1 walking speed for the poorest group.

H.26 Table HL6a shows the percentage of participants reporting difficulties with one or more ADLs by age category and sex. All groups show an increase in difficulties with ADLs from waves 1 to 6.

---

<sup>1</sup> Wave 3 is excluded because it used a different question.

<sup>2</sup> See footnote 1.

H.27 Table HL6b shows the percentage of participants reporting difficulties with one or more ADLs by wealth group and sex. In each group, the proportion of individuals experiencing difficulties with ADLs increases in each successive wave. Wealthier participants consistently have less difficulty with ADLs than poorer participants.

### **Cognitive function**

H.28 Table HL7a shows the mean recall scores for participants by baseline age category and sex. Memory performance remains stable or even improves over waves in people aged up to 65. In older age groups, however, there is a sustained decrease in recall over time.

H.29 Table HL7b shows the mean recall scores by wealth group and sex. The poorest groups show decreases in recall over time. However, recall scores remain stable for the wealthiest groups.

### **Health behaviours**

H.30 Table HL8a shows the prevalence of cigarette smoking by baseline age category and sex from waves 1 to 6. In general, the prevalence of smoking decreases over time. Prevalence remains stable among men aged 80+, while from wave 2 onwards no women aged 80+ smoked. Behaviour among men aged 60–64 shows less of a pattern and is possibly indicative of difficulties in quitting for this group.

H.31 Table HL8b shows the prevalence of smoking by baseline wealth group and sex. Each wealth group shows decreases in smoking prevalence over time.

H.32 Table HL9a shows the prevalence of sedentary behaviour or low physical activity by baseline age category and sex. For men and women, prevalence of low levels of activity increases with time. The declines in activity levels are relatively small among the younger groups but more marked for older age groups.

H.33 Table HL9b shows the prevalence of sedentary behaviour or low physical activity by baseline wealth group and sex. Poorer groups are less active at baseline. All groups show a decline in activity levels over time and the rate of decline appears similar across wealth groups.

### **Quality of life and depressive symptoms**

H.34 Table HL10a shows the mean quality of life score by baseline age category and sex. All age groups show decreases in quality of life over time. However, the decreases are fairly small among younger groups. Participants aged 65 and over show sharper declines in quality of life over the six waves.

H.35 Table HL10b shows the mean quality of life score by baseline wealth group and sex. All groups show similar declines in quality of life over time.

H.36 Table HL11a shows mean scores on the CESD scale by baseline age category and sex. There is no clear pattern of change in mean scores across time.

H.37 Table HL11b shows mean scores on the CESD scale by baseline wealth category and sex. At every wave, mean scores decrease with increasing wealth but there is no discernible pattern to changes over time within each wealth group.

## Nurse visit cross-sectional tables

### Anthropometry

H.38 Tables N1a and N1b show the mean body mass index and BMI categories by sex and age category at wave 6. The overall mean BMI in 2012–13 is similar for men (28.3 kg/m<sup>2</sup>) and women (28.5 kg/m<sup>2</sup>). Among men, mean BMI starts decreasing after the 65–69 age group, from 28.5 kg/m<sup>2</sup> to 27.4 kg/m<sup>2</sup> for those aged 80 years or over. In women, mean BMI also decreases after 65–69 years, from 28.7 kg/m<sup>2</sup> to 27.3 kg/m<sup>2</sup> for those aged 80 or over. Less than 1% of men and slightly over 1% of women are underweight. Just under a third of women and just over a fifth of men have BMI in the desirable category. A greater proportion of men (46.6%) than of women (34.5%) are overweight, and this applies to all age groups, but a greater proportion of women (34.6%) than of men (30.2%) are obese. The very oldest groups are the least likely to be obese.

H.39 Tables N1c and N1d show mean BMI and BMI categories by wealth group and sex. Mean BMI and the prevalence of obesity decrease with increasing wealth.

H.40 Table N2a shows mean waist circumference the prevalence of raised waist circumference by age category and sex. The mean waist circumference is 101.9 cm in men and 92.1 cm in women. Raised waist circumference is defined as 102 cm or greater in men and 88 cm or greater in women. Overall, 46.3% of men have raised waist circumference compared with 58.2% of women.

H.41 Table N2b shows mean waist circumference and the prevalence of raised waist circumference by wealth group and sex. In 2012–13, the prevalence of raised waist circumference falls with increasing wealth. The proportion of male participants with raised waist circumference rises from 41.7% for the wealthiest participants to 52.1% for the poorest. In women, this proportion rises from 45.9% for the wealthiest participants to 67.6% for the poorest.

### Blood pressure

H.42 Table N3a shows mean systolic (SBP) and mean diastolic (DBP) blood pressure by age category and sex. SBP and DBP are higher among men than women. Among men, SBP increases until age 79 and then there is a small decrease, while there appears to be a steady increase in SBP with age among women. Among both men and women, increased age is associated with decreases in DBP.

H.43 Table N3b shows mean SBP and DBP by wealth category and sex. Mean levels of SBP and DBP do not show a clear pattern of association with wealth.

### Lipid profile

H.44 Table N4a shows mean levels of total cholesterol, high-density lipoprotein (HDL) cholesterol, low-density lipoprotein (LDL) cholesterol and triglycerides by age category and sex. For each of these, the proportion of individuals reporting 'at-risk' values is also reported. At every age, men have lower levels of total cholesterol than women, and these levels decrease with age for men. Among women, there is a small decrease in the mean cholesterol levels with age. Overall, 58.8% of men and 75.6% of women have high total cholesterol levels (at least 5.0 mmol/l). The gender difference in raised total cholesterol is more pronounced in the older groups because the percentage with higher cholesterol declines sharply with age for men but more

gradually for women. Mean HDL cholesterol is higher for women than for men in every age category. Overall, mean HDL levels do not vary appreciably with age in either sex. ‘High-risk’ levels of HDL (less than 1.0 mmol/l for men and less than 1.2 mmol/l for women) are present in 7.7% of men and 6.6% of women and no consistent pattern of difference with age is seen in either sex.

The mean LDL cholesterol levels are slightly lower in men (3.26 mmol/l) than in women (3.48 mmol/l). In men, LDL concentrations decrease with age, while there is little pattern with age for women. In total, 60.8% of men and 68.2% of women have elevated levels of LDL cholesterol (at least 3.0 mmol/l). The prevalence of high LDL levels in men decreases with age, e.g. 73% of men aged 50–54 years compared with 50% of men aged 75–79 years. In women, the prevalence of high LDL also decreases with age. Mean triglycerides concentrations are 1.20 mmol/l in women and 1.34 mmol/l in men. In men, there is a decrease in mean levels by age. Elevated levels of triglycerides (at least 1.7 mmol/l) are present in 32.3% of men and 21.5% of women. The prevalence of high levels of triglyceride decreases with greater age in men, while a small increase with age is seen among women till the age of 70–74, followed by a decrease. Note that values for LDL and triglycerides are available only for participants who provided fasting blood samples (see AH.7).

H.45 Table N4b shows the lipid profile by wealth group and sex. Mean levels of total cholesterol and LDL cholesterol show a marked socio-economic gradient that is the reverse of what might be expected. Increasing wealth is associated with higher rather than lower levels of both total cholesterol and LDL cholesterol. However, fewer participants who are in the highest wealth group have levels of ‘good’ cholesterol (HDL) that would indicate increased risk. Similarly, levels of triglycerides decrease with increasing wealth.

### **Inflammatory markers**

H.46 Table N5a shows mean concentration levels of inflammatory markers fibrinogen and C-reactive protein (CRP) concentrations by age category for men and women. The mean levels of fibrinogen and CRP increase with age in both men and women.

H.47 Table N5b shows mean levels of fibrinogen and CRP by wealth group and sex. With increasing wealth, both fibrinogen and CRP levels decrease.

### **Glycated haemoglobin**

H.48 Table N6a shows the mean glycated haemoglobin (HbA1c) levels by age and sex. There is a small increase with age in both sexes. The mean rises from 5.62% in the youngest men to 6.07% in the oldest men, and from 5.83% to 6.03% in the same age groups for women.

H.49 Table N6b shows levels of glycated haemoglobin by wealth category and sex. Glycated haemoglobin is inversely related to wealth such that wealthier participants have lower levels of HbA1c.

### **Haemoglobin**

H.50 Table N7a shows mean haemoglobin levels and the percentage of individuals who are classified as anaemic by age category and sex. Mean levels of haemoglobin are higher in men than in women. For both sexes, there is a decrease in levels with age. Overall, 11.2% of men and 14.7% of women have low haemoglobin (anaemia).

In both men and women, there is a clear upward shift in the prevalence of anaemia at the oldest age groups. In men, the prevalence of anaemia increases from 5% in the youngest age group to 38% in the oldest age group, with substantial differences between those aged 75 years and over and younger men. Women show a similar pattern.

H.51 Table N7b shows mean levels of haemoglobin and the percentage of participants with anaemia in wave 6 by wealth group and sex. While mean haemoglobin levels do not differ appreciably by wealth group, the prevalence of anaemia is lower among participants in the highest wealth group.

### **Lung function**

H.52 Table N8a shows mean forced expiratory volume (FEV1), forced vital capacity (FVC) and peak expiratory flow rate (PEF) by age and sex-specific height group. These measures are all greater in men than in women and greater in taller people of either sex. Within each gender-specific height band, FEV1, FVC and PEF decrease with advancing age.

H.53 Table N8b shows FEV1, FVC and PEF by wealth group and sex-specific height group. For each of the measurements, a similar pattern is observed. Generally, as wealth increases, so does the lung function measure.

### **Insulin-like growth factor 1 (IGF-1)**

H.54 Table N9a shows the mean levels of IGF-1 by age category and sex. Overall, mean levels decrease with age. The prevalence of those in the lowest quintile of levels of IGF-1 increases considerably with age in both men (from just 11.6% for the 50–54 age group to 47.8% at 80 years and older) and women (from 15.3% for the 50–54 age group to 38.1% at 80 years and older).

H.55 Table N9b shows mean levels of IGF-1 by wealth group and sex. A socio-economic gradient is evident, such that there are increases in mean levels and decreases in the proportion in the lowest quintile with increased wealth.

### **Vitamin D**

H.56 Vitamin D was measured for the first time in wave 6 of ELSA (Table N10a). Overall, the mean levels of vitamin D are similar for both men and women. There also does not appear to be a consistent pattern of change with age.

H.57 Table N10b shows mean levels of vitamin D by wealth group and sex. A socio-economic gradient is observed, with levels increasing with increased wealth.

### **Grip strength**

H.58 Table N11a shows mean grip strength by age category and sex. A marked gender difference in grip strength is seen, with men having much higher mean grip strength at every age. For both sexes, there is a decrease in grip strength with increasing age.

H.59 Table N11b shows mean grip strength by wealth group and sex. Wealthier participants have higher mean grip strength.

## Nurse visit longitudinal tables

### Anthropometry

H.60 Tables NL1a and NL2a show mean levels of BMI and waist circumference for participants who provided data in the three nurse visits (2004–05, 2008–09 and 2012–13) by age category at wave 2 (2004–05) and sex. Increases are seen in both mean BMI and mean waist circumference from wave 2 to wave 4 but not from wave 4 to wave 6. These increases from wave 2 to wave 4 are apparent for men and women in all age groups.

H.61 Tables NL1b and NL2b show mean BMI and waist circumference at waves 2, 4 and 6 by wealth group at wave 2 and sex. All wealth groups show an increase in BMI and waist circumference over time.

*Note that values presented here may differ from those show in Chapter 4, 'Trends in obesity among older people in England' as the analyses presented in the chapter use imputed data for BMI and waist circumference (see Section 4.2.5).*

### Blood pressure

H.62 Tables NL3a and NL4a show mean levels of SBP and DBP at waves 2, 4 and 6 by sex and wave 2 age category. Over time, all age groups show a decrease in their mean diastolic blood pressure and this trend is evident for both men and women. For women aged between 52 and 64, there is an increase in systolic blood pressure over time, while older groups show a decrease in SBP over time. Change patterns for SBP are less clear among men.

H.63 Tables NL3b and NL4b show mean levels of SBP and DBP by sex and wave 2 wealth category. All wealth groups show decreases in blood pressure over time, except women in the highest wealth group, who show a decrease in DBP only.

### Lipid profile

H.64 Tables NL5a, NL6a, NL7a and NL8a show mean lipid levels by age category and sex. Total cholesterol, LDL cholesterol and triglycerides decrease from wave 2 to wave 6 in both men and women, while HDL cholesterol increases.

H.65 Tables NL5b, NL6b, NL7b and NL8b show mean cholesterol levels by sex and wave 2 wealth group. All wealth groups show decreases over time in total cholesterol, LDL cholesterol and triglycerides, with decreases being more marked among lower wealth groups. HDL cholesterol increases over time in all groups.

### Inflammatory markers

H.66 Tables NL9a and NL10a show levels of C-reactive protein (CRP) and fibrinogen by sex and wave 2 age category. For most age groups, CRP levels increase between waves 2 and 4 and then decrease. However, men aged 70–79 and women aged 65–74 at wave 2 show sustained decreases in CRP levels. In contrast, fibrinogen levels show a pattern of increase between waves 2 and 4 followed by a decrease for all age groups.

H.67 Tables NL9b and NL10b show levels of inflammatory markers by sex and wave 2 wealth category. Among men, the poorer groups show a sustained decrease in CRP levels over time, while the three wealthiest groups show an increase between waves 2 and 4 followed by a decrease. The pattern is less clear for women. For all

wealth groups, levels of fibrinogen show a pattern of increase between waves 2 and 4 followed by a decrease.

### **Glycated haemoglobin**

H.68 Table NL11a shows glycated haemoglobin levels over time by sex and wave 2 age category. Mean levels of glycated haemoglobin increase from wave 2 to wave 6 in all age categories for both men and women.

H.69 Table NL11b shows glycated haemoglobin levels over time by sex and wave 2 wealth category. All wealth groups show an increase in mean glycated haemoglobin levels over time.

### **Haemoglobin**

H.70 Table NL12a shows mean haemoglobin levels over time by sex and wave 2 age category. All age groups show a sustained decrease in haemoglobin levels over time.

H.71 Table NL12b shows mean haemoglobin levels over time by sex and wave 2 wealth category. All wealth groups show a decrease in haemoglobin levels over time.

### **Lung function**

H.72 Tables NL13a, NL14a and NL15a show lung function measures by sex-specific height group and wave 2 age category. Mean forced vital capacity (FVC), forced expiratory volume (FEV1) and peak expiratory flow rate (PEF) decrease between waves 2 and 6. These tests also show that they are all greater in men than in women and greater in taller people of either sex. Within each gender-specific height band, FVC, FEV1 and PEF decrease with advancing age.

H.73 Tables NL13b, NL14b and NL15b show FVC, FEV1 and PEF by sex-specific height group and wealth group. For each measure, participants in the highest wealth group have higher values at wave 6 than participants from the lowest wealth group have at wave 2.

### **Insulin-like growth factor 1 (IGF-1)**

H.74 Table NL16a shows IGF-1 levels in wave 4 and wave 6. Mean levels of IGF-1 generally increase for women and decrease for men between the waves.

H.75 Table NL16b shows IGF-1 levels in waves 4 and 6 by wealth group and sex. For men, most wealth groups show an increase in IGF-1 levels over time, while the opposite trend is seen for women.

### **Grip strength**

H.76 Table NL17a shows mean grip strength from waves 2 to 6 by sex and wave 2 age category. All age groups show a decline in grip strength over time, with older groups (particularly among men) showing a slightly faster decline.

H.77 Table NL17b shows mean grip strength from waves 2 to 6 by sex and wave 2 wealth group. A similar decline in grip strength is shown by all wealth groups across the three waves.

## Annex AH. Definitions

AH.1 *Activities of daily living (ADLs) and instrumental activities of daily living (IADLs)*: Respondents were asked if they had any difficulty with any of the following because of a mental, physical, emotional or memory problem: dressing, including putting on shoes and socks; walking across a room; bathing or showering; eating, such as cutting up food; getting into or out of bed; using the toilet, including getting up or down; using a map to figure out how to get around in a strange place; shopping for groceries; making telephone calls; taking medication; doing work around the house or garden; or managing money, such as paying bills and keeping track of expenses. Participants were asked not to consider any condition that would last less than 3 months. The first six items relate to ADLs while the remaining items relate to IADLs. Based on responses to these items, separate variables indicating whether the participant had difficulties with one or more ADLs/IADLs were computed.

AH.2 *Age*: Defined as age at last birthday. For all results presented here, age was categorised into five-year age bands ranging from 50–54 to 80+.

AH.3 *Alcohol consumption*: Daily drinking was defined as drinking on 3 days a week or more.

AH.4 *Balanced panel*: This is the sample used in the longitudinal tables (HL1 to HL11) and includes core sample participants from wave 1 who provided data on the relevant measure at all follow-up waves. For the nurse data longitudinal tables (NL1 to NL17), this refers to the sample who provided nurse data at each of the three nurse visits.

AH.5 *Baseline*: This refers to the wave of data that is the starting point for characteristics in longitudinal analysis. For results here, this is either wave 1 (longitudinal tables) or wave 2 (nurse visit longitudinal tables).

AH.6 *Blood pressure*: The systolic arterial pressure is defined as the peak pressure in the arteries, which occurs near the beginning of the cardiac cycle. The diastolic arterial pressure is the lowest pressure at the resting phase of the cardiac cycle. Systolic (SBP) and diastolic (DBP) blood pressure were measured using a standardised method. In adults, hypertension is defined as having SBP of at least 140 mmHg or having DBP of at least 90 mmHg or being on medication to control hypertension. All respondents were eligible for the blood pressure module, except those who were pregnant. Three readings were collected at one-minute intervals (systolic, diastolic and pulse rate) using the Omron HEM-907 equipment. It was ensured that the room temperature was between 15°C and 25°C. The respondent was asked not to eat, smoke, drink alcohol or take vigorous exercise in the 30 minutes preceding the blood pressure measurement as blood pressure can be raised immediately after any of these activities.

AH.7 *Blood sample*: Blood samples were taken from willing ELSA core members, except those who had a clotting or bleeding disorders (e.g. haemophilia and low platelets), had ever had a fit, were not willing to give their consent in writing, or were currently on anticoagulant drugs (e.g. warfarin therapy). Fasting blood samples were taken whenever possible. Respondents over 80 years, those known to be diabetic and on treatment, those with a clotting or bleeding disorder or on anti-coagulant drugs (e.g. warfarin), those who had ever had fits, those who seemed frail, or respondents whose health was a cause for concern for the nurse were not asked to fast. Subjects

were considered to have fasted if they had not had food or drink except water for a minimum of 5 hours prior to the blood test.

The amount of blood taken from each participant in order to analyse each biomarker is presented below:

- 1 citrate blue tube (1.8ml) – fibrinogen;
- 1 plain red tube (6ml) – total and HDL cholesterol, triglycerides, C-reactive protein (CRP), insulin-like growth factor 1 (IGF-1);
- 1 fluoride grey tube (2ml) – fasting glucose (*values not reported here*);
- 1 EDTA light purple tube (2ml) – haemoglobin and glycated haemoglobin;
- 2 EDTA dark purple tubes (4ml) – genetics.

All the blood samples were analysed at the Royal Victoria Infirmary laboratory in Newcastle.

**AH.8 *Body mass index (BMI)*:** This is a widely-accepted measure of weight for height and is defined as weight in kilograms divided by the square of the height in metres ( $\text{kg}/\text{m}^2$ ). BMI was calculated for all those respondents for whom both a valid height and weight measurement were recorded. BMI scores were categorised as follows:

- underweight group ( $<18.5 \text{ kg}/\text{m}^2$ );
- normal ( $\geq 18.5$  and  $<25 \text{ kg}/\text{m}^2$ );
- overweight ( $\geq 25$  and  $<30 \text{ kg}/\text{m}^2$ );
- obese ( $\geq 30 \text{ kg}/\text{m}^2$ ).

**AH.9 *Centre for Epidemiologic Studies depression (CESD) scale*:** This scale is a brief measure of depressive symptoms. Participants are asked whether they had experienced any of the eight symptoms in the past 4 weeks. The total score ranges from 0 to 8. A cut-off of 4 or more points is used to classify individuals as being depressed.

**AH.10 *Cholesterol*:** Cholesterol is a type of fat present in the blood and is related to diet. Too much *total cholesterol* in the blood increases the risk of heart disease. *High-density lipoprotein (HDL) cholesterol* is ‘good’ cholesterol, which is protective for heart disease. *Low-density lipoprotein (LDL) cholesterol* is ‘bad’ cholesterol and a risk factor for cardiovascular disease. *Triglycerides*, in combination with total and HDL cholesterol, provide a lipid profile, which can give information on the risk of cardiovascular disease. Measures of LDL and triglycerides were only taken for participants who were asked to fast.

**AH.11 *C-reactive protein (CRP)*:** The level of this protein in the blood gives information on inflammatory activity in the body and is also associated with risk of heart disease.

**AH.12 *Depression*:** See Centre for Epidemiologic Studies depression (CESD) scale (AH.9).

**AH.13 *Fibrinogen*:** This is a protein necessary for blood clotting. High levels are also associated with a higher risk of heart disease.

**AH.14 *Fluid intelligence*:** This refers to a general ability to solve problems. This was measured for the first time in this wave of ELSA (wave 6) using a number series task which relies on the participant being able to reason with concepts that are based on mathematical relationships. The tasks were adaptive, and progressively increased or

decreased in difficulty based on performance. The final score takes into consideration the difficulty level of the questions and the number of correct responses. Higher scores are indicative of greater levels of fluid intelligence.

AH.15 *Fruit and vegetable consumption*: Participants were asked about their fruit and vegetable consumption and, based on this, the total number of portions of fruit and vegetable consumed was computed. This was then dichotomised to indicate whether participants ate fewer than five portions a day or at least five portions a day.

AH.16 *Glycated haemoglobin (HbA1c)*: This indicates the presence or risk of type 2 diabetes, which is associated with an increased risk of heart disease.

AH.17 *Grip strength*: The grip strength test is a measure of upper body strength. The test was given to all respondents who were willing to take it, with no upper or lower age limits. Participants were, however, excluded if they had swelling or inflammation, severe pain or a recent injury, or if they had had surgery to the hand in the preceding six months. If there was a problem with only one hand, measurements were taken using the other hand. After adjusting the gripometer (grip gauge) to suit the respondent's hand and positioning the respondent correctly, the respondent was asked to squeeze the gripometer as hard as they could for a couple of seconds. Three values were recorded for each hand, starting with the non-dominant hand and alternating between hands. Any measurements carried out incorrectly were not included. The gripometer used was the 'Smedley's for Hand' Dynamo Meter, with a scale ranging from 0 to 100 kg. The average of three measurements (in kilograms) is reported here.

AH.18 *Haemoglobin*: This is a measure of iron levels in the body and is related to diet and other factors. Anaemia is defined as having a haemoglobin level below 13 g/dl for men and below 12 g/dl for women.

AH.19 *Health conditions*: Based on participants' reports of doctor-diagnosed health conditions, variables were derived indicating whether participants had *ever* been diagnosed with each of the health conditions.

AH.20 *Height*: Height was measured using a portable stadiometer with a sliding headplate, a base plate and three connecting rods marked with a metric scale. Respondents were asked to remove their shoes. One measurement was taken with the respondent stretching to the maximum height and with the head in the Frankfort plane.<sup>3</sup> The reading was recorded to the nearest millimetre.

AH.21 *Insulin-like growth factor 1 (IGF-1)*: This is a hormone that helps control reactions to stress and regulate various body processes including digestion, the immune system, mood and energy usage.

AH.22 *Limiting long-standing illness*: Respondents were asked whether they suffered from a long-standing illness and whether this condition limited their activities in any way. Responses to both items were combined to create a variable indicating whether a participant suffered from a limiting long-standing illness or not.

AH.23 *Lipid profile*: See Cholesterol (AH.10).

AH.24 *Lung function measures*: These tests are commonly used in clinical practice to assess impairment due to chronic lung disease and asthma. Lung function is poorer

---

<sup>3</sup> The Frankfort plane is an imaginary line passing through the external ear canal and across the top of the lower bone of the eye socket, immediately under the eye. This line must be parallel with the floor. This gives the maximum vertical distance from the floor to the highest point of the skull.

among older adults and among smokers. For these tests, respondents were excluded if they had had abdominal or chest surgery in the preceding 3 weeks, had been admitted to hospital with a heart complaint in the preceding 6 weeks, had had eye surgery in the preceding 4 weeks, had a tracheotomy, or were pregnant. Further, the tests were not done if the ambient temperature was less than 15°C or more than 35°C, as this affects the accuracy of the readings. The measures of lung function obtained at the nurse visit were:

- *forced expiratory volume (FEV1)*: the volume in litres expelled in the first second of a forced expiration, starting from a maximum inspiration;
- *forced vital capacity (FVC)*: the full volume in litres expelled following a maximum inspiration;
- *peak expiratory flow rate (PEF)*: the fastest rate of exhalation (in litres per minute) recorded during the measurement.

The protocol requires three measurements and the highest satisfactory score is taken as the valid one. High values indicate better lung function. The equipment used in waves 2 and 4 consisted of a spirometer (Vitalograph Micro), disposable cardboard mouthpieces and a 1 litre calibration syringe. For wave 6, the NDD Easy On-PC spirometer was introduced.

*AH.25 Nurse visit*: All core members were eligible for a nurse visit in person (i.e. not by proxy) either in a private household or in an institution. A nurse visit was provided to only those partners who explicitly requested a nurse visit. The CAPI (computer-assisted personal interview) program was used. After the main interview, the interviewer made an appointment for the nurse to visit the respondent or set up contact between nurse and respondent. The nurse visit consisted of a series of measurements that were only obtained if the appropriate consents were obtained and the respondent was able to respond affirmatively to relevant safety questions. The nurse visit included several standard measures including anthropometric measures, blood pressure, blood sample and lung function.

*AH.26 Physical activity*: Participants were asked how often they participated in mild, moderate or vigorous physical activity. Based on their responses, they were classified as being sedentary or reporting low physical activity (versus moderate or vigorous physical activity).

*AH.27 Quality of life*: This was measured using the CASP questionnaire, which assesses four dimensions of quality of life particularly relevant to older adults (**C**ontrol, **A**utonomy, **S**elf-realisation and **P**leasure).

*AH.28 Recall*: This is a score computed on the basis of the cognitive function tests. Participants were presented with a list of 10 common words. After this, participants were asked to recall as many words as they could (immediate recall). They were also asked to recall these words after an interval during which they carried out other tasks (delayed recall). The sum of words correctly recalled during the immediate and delayed recall tasks is the recall score.

*AH.29 Self-rated health*: Participants were asked whether they would rate their health as *excellent*, *very good*, *good*, *fair* or *poor*. Wave 3 used a different question and hence is not included in the longitudinal tables for self-rated health.

*AH.30 Smoking status*: This related to current smoking status.

AH.31 *Vitamin D*: This is a vitamin that helps regulate calcium and phosphorus levels in the body. Vitamin D is primarily produced in the skin through exposure to sunlight but is also present in some foods, such as eggs, dairy products and fish. In winter, especially in countries with limited sunlight, vitamin D production is reduced and hence supplementation may be necessary. This is particularly true of older adults or those who may be restricted to their homes.

AH.32 *Waist circumference*: The waist was defined as the midpoint between the lower rib and the upper margin of the iliac crest. Waist circumference was measured using a tape with an insertion buckle at one end. The measurement was taken twice, using the same tape, and was recorded to the nearest even millimetre (mm). Those whose waist circumference measurements differed by more than 3 cm had a third measurement taken. The mean of the two valid measurements (the two out of the three measurements that were closest to each other, if there were three measurements) were used in the analysis. Waist circumference was categorised into three main groups using sex-specific cut-offs:

- low risk (<94 cm for men and <80 cm for women);
- medium risk ( $\geq 94$  cm and <102 cm for men;  $\geq 80$  cm and <88 cm for women);
- high risk ( $\geq 102$  cm for men and  $\geq 88$  cm for women).

Waist circumference may be a better measure than BMI (see AH.8) for identifying those at risk because of their body shape. Fat distribution differs considerably between younger and older people and abdominal fat tends to increase with age. Therefore waist circumference can be considered an appropriate indicator of body fatness and central fat distribution among the elderly.

AH.33 *Walking speed*: This was computed based on the timed walk test. Participants aged 60 years and over were asked to walk a distance of 8 feet (2.44 metres) twice and timed. The mean of the two speeds is reported here, measured in metres per second (m/s).

AH.34 *Wealth group*: To form wealth groups, we order all ELSA sample members according to the value of their total (non-pension) family wealth – which includes financial wealth from savings and investments minus debts, physical wealth (wealth held in second homes, farm or business property, other business wealth, other land and other assets such as jewellery or works of art or antiques) minus debts, and housing wealth minus mortgages – and divide the sample into five equal-sized groups. Where analysis is carried out using all ELSA sample members, the groups are equal in size and can be referred to as quintiles. Much of the analysis in this chapter is carried out using subsamples of the ELSA population. Where analysis does not use the whole ELSA sample, the groups are unequal in size and are more accurately referred to as ‘wealth groups’. For consistency reasons, we use the term ‘wealth group’ rather than ‘wealth quintile’ throughout the chapter. The cut-off points for the wealth groups are shown in the following table, reported in January 2013 prices and rounded to the nearest £1,000:

	Wealth group definition, wave 1 (2002–03)	Wealth group definition, wave 6 (2012–13)
Lowest	Less than £19k	Less than £48k
2 <sup>nd</sup>	Between £19k and £130k	Between £48k and £170k
3 <sup>rd</sup>	Between £130k and £226k	Between £170k and £273k
4 <sup>th</sup>	Between £226k and £400k	Between £273k and £450k
Highest	More than £400k	More than £450k

## *Health domain tables*

AH.35 *Weight*: Weight was measured using a portable electronic scale. Respondents were asked to remove their shoes and any bulky clothing. A single measurement was recorded to the nearest 0.1 kg. Respondents who weighed more than 130 kg were asked for their estimated weights because the scales are inaccurate above this level. These estimated weights were included in the analysis.

### **AH.36 Notes to all tables**

The unit of observation in all tables is the individual.

The health status cross-sectional tables (H1 to H9) are based on participants who were present at wave 6 of ELSA including refreshment sample members, while the nurse visit cross-sectional tables (N1 to N11) are based on those from the above sample who agreed to the nurse visit.

Health status longitudinal tables (HL1 to HL11) are based on participants who were present at each wave of ELSA from wave 1 to wave 6, while the nurse visit longitudinal tables (NL1 to NL17) are based on participants who were present at the nurse visit at waves 2, 4 and 6.

All results, with the exception of the nurse visit longitudinal tables (NL1 to NL17), are based on weighted data. Only unweighted frequencies (N) for each group are presented.

The fieldwork timetable is as follows:

	<b>Fieldwork dates (inclusive)</b>
Wave 1	March 2002 – March 2003
Wave 2	June 2004 – June 2005
Wave 3	May 2006 – August 2007
Wave 4	June 2008 – July 2009
Wave 5	July 2010 – June 2011
Wave 6	May 2012 – May 2013

Table H1a. Self-rated health (%), by age and sex: wave 6

	Age in 2012–13							All
