The temporary VAT cut

- Standard rate of VAT cut from 17.5% to 15% from Dec 1st 2008 to Dec 31st 2009. Announced November 24, 2008.
- If passed on to consumers, this would lowers the current price of applicable goods by 2.5 percentage points.
- About 55% of gross consumer expenditure is on goods to which the standard rate of VAT applies; this implies that about 51% of net expenditure is subject to the standard rate of VAT.
- Assuming limited within-period substitution (and full-pass through), the VAT cut should reduce the price of current purchases by 1.275 percentage points or 1.2%
- This was intended to stimulate current consumer demand.
- Estimated cost about £12.4 billion (about 2% of revenues).
The economic situation was rapidly worsening
Base rate changes not reflected in borrowing rates

Nominal Monthly Interest rate of UK Resident Banks

Household Deposit Interest Rate

Source: Bank of England
Reactions were mixed....

• “The VAT cut has been an unbelievable and expensive failure. This government, that lectured us about prudence, has spent £12.5bn of our money, and wasted it.” - David Cameron, Leader of the Conservatives

• “Temporarily cutting VAT, a measure that was adopted in Great Britain, does not seem to me to be a good idea – 2% less is not perceived by consumers as a real incentive to spend.” - Olivier Blanchard, Chief Economist at the IMF

• “I doubt if it is wise to put too much stress on devices for causing the volume of consumption to fluctuate. A remission of taxation on which people could only rely for an indefinitely short period might have very limited effects in stimulating their consumption.” Keynes, 1943
How should it work?

• Like all price changes, a temporary VAT cut has income and substitution effects

• The income effect arises because, with unchanged purchasing, consumers have money left in their pockets

• Substitution effects of the anticipated increase in prices. Lower prices today relative to tomorrow give consumers an incentive to bring forward spending.
How should it work? Cont’d.

- There are two kinds of substitution effects
- Consumers may bring forward consumption; this is the standard inter-temporal substitution of consumption
  - Applies throughout the period
- In addition, consumers may bring forward purchases of non-perishable (or storable) goods to be consumed later. These are “arbitrage effects”.
  - May occur mostly at the end of the period
- An important category of non-perishable goods is durables. Durables are about a third of spending to which the standard VAT rate applies.
How big is the income effect?

• For unconstrained consumers, the income effect should be small. The government faces an inter-temporal budget constraint.
• Thus for unconstrained consumers, the substitution effect dominates.
• Constrained households should increase purchases in proportion to the fall in current prices (an elasticity of 1). Thus an increase of about 1.2% in volume of purchases
How big is the substitution effect?

• A mid-point estimate of the elasticity of inter-temporal substitution for **nondurable** consumption is 0.75. (Attanasio and Wakefield, 2008).

• Luxuries are easier to postpone (Browning and Crossley, 2000). Goods not subject to the standard VAT rate are mostly necessities. This suggests a somewhat larger elasticity.

• Arbitrage effects in durable and other non-perishable goods could make the elasticity of inter-temporal substitution for expenditure larger still.

• An elasticity of one seems reasonable.
Summary

- Constrained households should increase purchases in proportion to the fall in current prices. Thus an increase of about 1.2% in volume of purchases.
- Assuming an inter-temporal substitution elasticity (for expenditure) of one, unconstrained households should do the same.
- The effect might be a bit smaller if there is less than full pass through; it might be a bit larger if there are significant arbitrage effects.
- On balance, an increase in the (counterfactual) growth rate of the volume of sales/purchases of about 1 percent point seems likely. Compares well with some other stimulus options (eg., tax refunds.)
- Slightly regressive.
- Key issues are 1) pass-through, 2) salience, and 3) intertemporal responses
The evaluation problem

- To evaluate an intervention, we need to do two things:
  - Measure an outcome, and
  - Construct a counterfactual.
- Both are very difficult in this context.
## Outcome measures - summary statistics

1) Pass-through

- There is a range of theoretical possibilities; imperfect competition does not necessarily imply less than full pass-through.
- Crossley, Low and Wakefield (2009) take full pass-through as a working assumption. With rapidly collapsing demand, retailers may be strongly motivated to maintain sales.

  source:  
  www.tesco.com  
  Dec. 3rd, 2008

- Blundell (2009) reviews the literature on pass-through and suggests that 0.75 might be a reasonable estimate.
Pass through (Cont’d)

- The *timing* of pass-through is also critical: in a sticky-price model, a VAT cut can lead to deflationary expectations. (For example, Eggertsson and Woodfood, 2004).

- Thus if prices are sticky, there is risk of dampening current demand; in this case, a VAT increase stimulates demand.

- Pike, Lewis and Turner (ONS, 2009): estimate that the CPI 12-month rate to December 08, published as 3.1%, would have been around 0.5% higher, had there been no reduction in VAT.

- Implies pass-through of a bit less than 50%. Essentially a “difference” estimate.
More evidence on VAT cut pass-through

- We adopt the approach in Carare and Danninger, (2008 IMF working paper)
- We evaluate whether the inflation dynamics of the RPI items subject to the standard VAT rate is different from that of the non-VAT items across the VAT cut, having controlled for time trends and seasonal effects.
- 64 RPI 2-digit items, Jan 05- Jun 09
- Sample consists of
  - 28 treated items (standard vat rate)
  - 36 control items (Non-VAT items + 5 standard rate items with an offsetting excise change)
### Pass-through results

2) Tax Salience

- Is a 2.5% cut in VAT is salient enough to induce consumers to bring forward purchases?
- Recent research (Chetty, Looney and Kroft, 2009) found that consumers significantly under-react to taxes that are not included in posted prices.
- VAT is included in posted prices (for most goods), but...

Salience: evidence from a consumer confidence survey?

- Nationwide Consumer Confidence Index conducted for Nationwide by TNS
- Started in May 2004
- 1,000 adults interviewed each month, with the sample structured to be nationally representative of all adults in term of age, sex and socio-economic group.
- The Consumer Confidence Index is based on responses to 5 questions about present situation (economic conditions and employment conditions) and expectations (economic conditions, employment and family income 6 months hence)
Spending questions

- The survey also asks two questions about spending:

- **Q1 Major Purchases**: Taking into consideration the cost of things today and the financial situation in general, to what extent would you say that now is a good or bad time to make a big purchase such as a house or flat, or a car?

- **Q2 Household Appliances**: To what extent would you say that now is a good or bad time to buy household appliances such as a washing machine, a refrigerator, a TV set and such like?

  - Would you say now is
    - A very good time to buy
    - A fairly good time to buy
    - Not good and not bad - about average
    - A fairly bad time to buy
    - A very bad time to buy
    - Don't Know (DO NOT READ OUT)

- We focus on Q2

3) Spending Response

- Although earlier micro (aggregate data) studies (e.g., Hall, 1988) suggest a small elasticity of inter-temporal substitution (EIS), micro–estimates of the EIS for nondurable consumption centre around 0.75 (Attanasio and Wakefield, 2008).
- Stocking-up in response to super-market sales is well documented (e.g., Boizot et al., 2001, Hendel and Nevo, 2004).
  - Correlation between price and quantity is negative.
  - Correlation between inter-purchase time and past price is negative.
- Barrell and Weale (2009) provide some evidence of inter-temporal substitution in response to previous VAT changes in Europe.
- Very large arbitrage effects bring a subsequent “hangover” (e.g. Car-scrapage schemes); there is a risk that this dampens a nascent recovery.
Spending response, cont’d

- Constant elasticity case is special (Browning and Crossley, 2000) and rejected by data (Crossley and Low, 2009).
- However, business cycle variation in “arbitrage effects” surely more important.
- Arbitrage effects moderated by storage costs, financing costs and by uncertainty. Uncertainty particularly important with irreversible purchases (option value).
- Same for households? Good evidence that household income uncertainty rises in recessions: Storesletten, Telmer and Yaron (2004); Blundell, Pistaferri and Preston (2008); Blundell, Low and Preston (2008).
- Financing costs may also be very different in a deep recession.
Not much evidence on response of durables and non-food non-perishables, and especially on how responses might vary with economic conditions.

Note: Standard errors are Newey-West

- Difficult to rationalize the time pattern with a model.
Conclusions

• Price data are consistent with substantial and rapid pass-through; our point estimate is 75%, though the confidence interval is large. No evidence of deflationary effect on expectation.

• Salience may be an issue, particularly as many prices were changed at the till.

• Survey data indicate a sharp change in consumer’s spending sentiment immediately after the VAT cut. This may indicate that the policy was salient.

• Strong retail sales growth immediately after introduction, but difficult to draw strong conclusions.
Extra Slides
Research agenda

• More data, and tax increase in December 2009 (but evaluation still difficult).
• Tax salience
• Pass-through
  – Pass-through will clearly vary with demand conditions in different markets
  – More structural approach required. Dynamics important.
• Inter-temporal substitution, particularly durables and other non-perishable goods.
  – Important to understand how large “arbitrage effects” might be, and how they are moderated by uncertainty.
How should it work? Cont’d.

- The change in relative prices is analogous to a cut in the real interest rate (assuming full-pass through in both cases).
- However, the income effects can be different.
- Simple 2 period intuition: nondurable consumption, CRRA preferences, EIS = $\theta$:

$$u(c_t) = \frac{(c_t)^{1-(1/\theta)}}{1-(1/\theta)}$$
How should it work? Cont’d.

unconstrained/forward looking:

\[(1 + t_1)c_1 + \left( \frac{1 + t_2}{1 + r} \right)c_2 \leq W_0 + y_1 + \frac{1}{1 + r}y_2\]

\[\Delta \ln (1 + t_1) \approx -1.2\]

\[\ln c_1 = -\theta \ln (1 + t_1) - \theta \ln \lambda\]

\[\Delta \ln c = \theta \left[ \ln (1 + r) + \ln (1 + t_1) - \ln (1 + \delta) - \ln (1 + t_2) \right]\]

liquidity constrained:

\[(1 + t_1)c_1 = W_0 + y_1 \quad \Rightarrow \quad \frac{\partial \ln c_1}{\partial \ln (1 + t_1)} = -1\]
Consumer Confidence Index – further details

- 3 response options for each question: POSITIVE, NEGATIVE and NEUTRAL.
- For each question, the POSITIVE figure is divided by the sum of the POSITIVE and NEGATIVE to yield a "RELATIVE" value.
- The RELATIVE for May 2004 is then used as a benchmark to yield the INDEX value for that question.
- Consumer Confidence Index is the average of all 5 Indexes.
- Present Situation Index is the average of Indexes for question 1 and 3
- Expectation Index is the average of Indexes for question 2, 4, and 5
Responses to Household Appliances Question

- Good
- Neither Good or Bad
- Bad
- Don't Know

© Institute for Fiscal Studies
The graph in this page and next are from the same data set (responses for household appliance question). The difference is in the order of the response and the format of the graphs.

Janjala Chirakijja, 11/09/2009
Spending response, cont’d

• Constant elasticity case is special (Browning and Crossley, 2000) and rejected by data (Crossley and Low, 2009).

\[ u(c_t) = \left( \frac{c_t - c}{1 - (1/\theta)} \right) \]

\[ \Delta \ln c_{t+1} = \alpha + \left( \frac{c_t - c}{c_t} \right) \theta \ln(1 + r_{t+1}) + u_{t+1} \]

• However, business cycle variation in “arbitrage effects” surely more important
