Royal Society, London

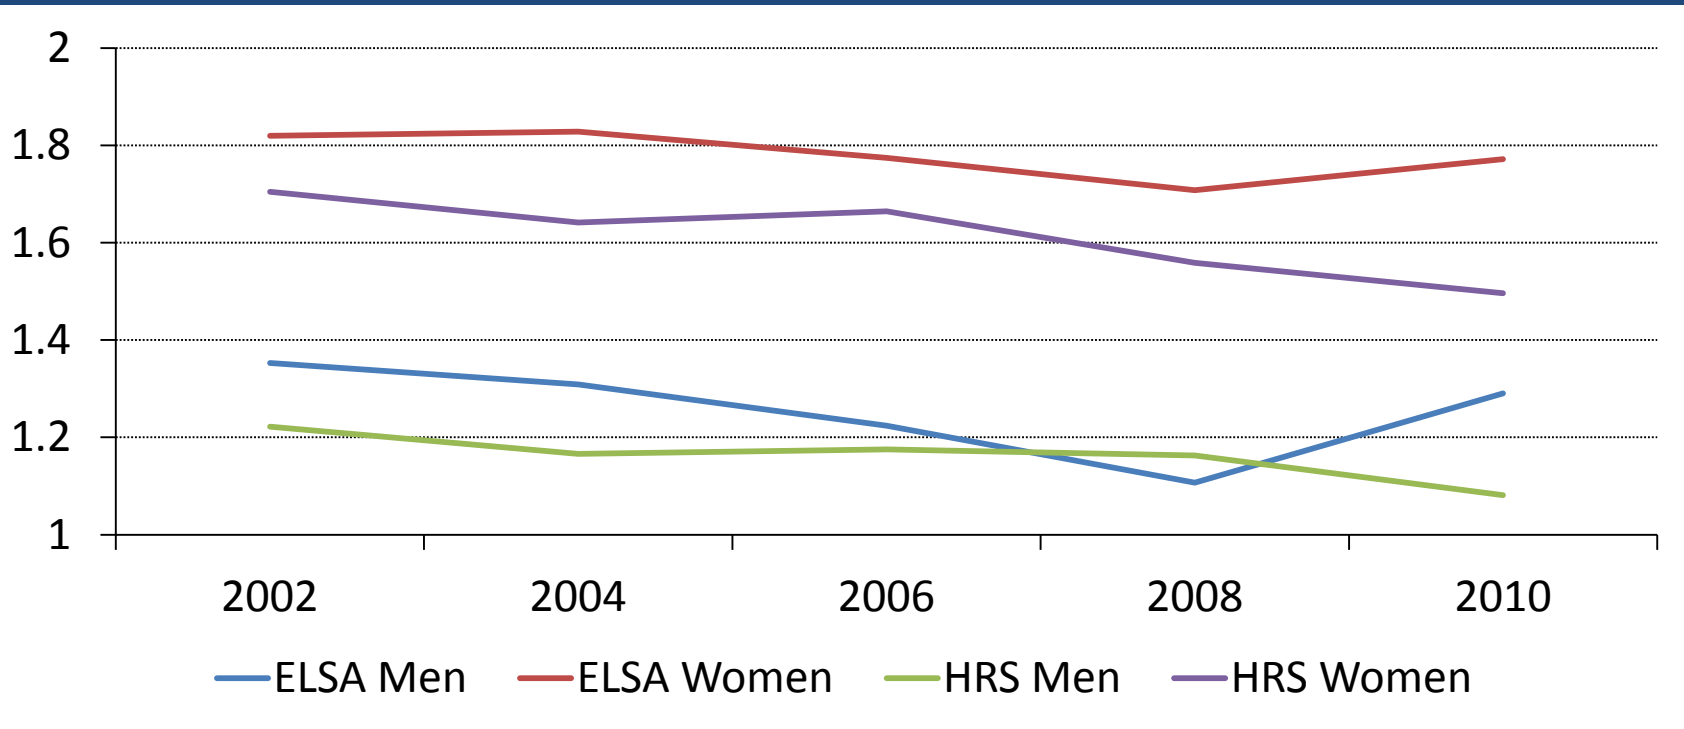

Introduction

- Why study depression ...
 - ... in later life?
 - ... longitudinally?
 - ... comparatively?

Sorrowing old man, Vincent Van Gogh, 1890

Departing from two findings

- More depression among women than men (Piccinelli & Wilkinson 2000)
- More depression in England than US (Weissman et al 1996, Zivin et al 2010)

Possible explanations

1. Measurement instrument functions differently?
2. Difference in associations between social factors and depressive symptoms?
3. Background context effects?

Theoretical expectations

- Depression is not a monolithic disease, but an emotional disorder accompanied by physiological symptoms...
 - > Mood (feeling sad, not enjoying life, ...)
 - > Somatic symptoms (tiredness, sleep problems, ...)
- Somatic symptoms not unique to depression, but also related to chronic illnesses, cognitive impairment, general stresses of later life (Parmelee, 2007)

Centre for Epidemiological Studies Depression scale (CESD)

- (Much of the time during past week),
 - You felt depressed?
 - You felt that everything you did was an effort?
 - Your sleep was restless
 - You were happy
 - You felt lonely
 - You enjoyed life
 - You felt sad
 - You could not get going
- Answer with Yes/No

1. Measurement

- Multiple Group Confirmatory Factor Analysis (MGCFA)
- ... CFA?
 - A 'theory-driven' way to measure latent concepts through observed indicators
 - Theory-driven because the relations are specified before doing analysis
 - Latent concepts -> values / diseases
 - Observed indicators -> items / symptoms / ...
- ... Multiple group?
 - Because we want to investigate the latent concept in several groups (countries/gender), and want to see if the structure between indicators and concept is the same in the different groups

Results MGCFA

(wlmsv estimation on 2002 ELSA/HRS data)

| Whole sample | RMSEA | CFI |
|-------------------------------------|-------|------|
| CES-D scale (1 factor) | .075 | .965 |
| Mood and Somatic factor (2 factors) | .052 | .984 |

| By country and gender (4 groups) 2 factor model (Mood & Somatic) | RMSEA | CFI |
|---|-------|------|
| Configural invariance | .055 | .982 |
| Metric invariance | .056 | .977 |
| Scalar invariance | .056 | .977 |

Note: Fit indices RMSEA: good fit if $<.06$
CFI good fit if $>.95$
(Hu & Bentler 1999)

Results Measurement

- > Depression is best measured using 2 separate scales, one for mood and one for somatic symptoms
- > Scales are equivalent over gender and country
- > Differences between countries and genders are not due to differential functioning of scale items

2. Differential associations

- Method:
 - Panel-data : multiple observations for each person
 - > Multilevel growth model to account for changes over time within individuals
- We do not want to impose a threshold on the number of symptoms needed to be categorised as depressed
 - > Count data instead of categorical approach

Mood Symptoms

mean = .7046; overdispersion = 2.546

Somatic Symptoms

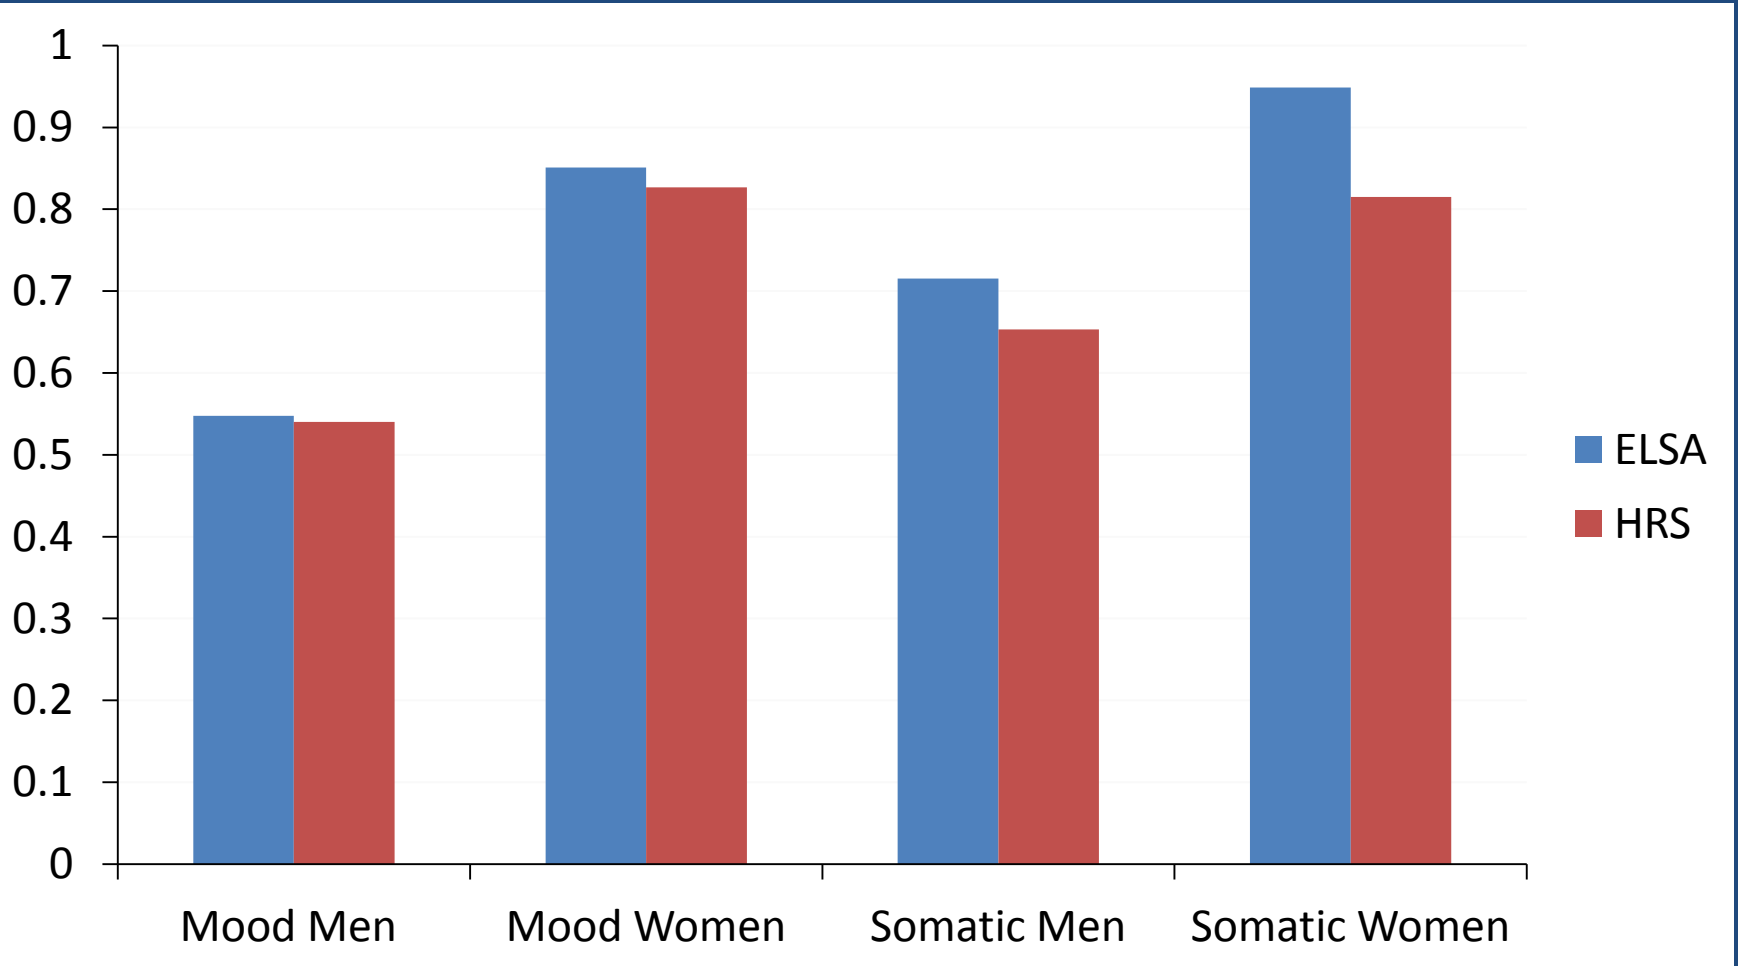

mean = .7778; overdispersion = .3677

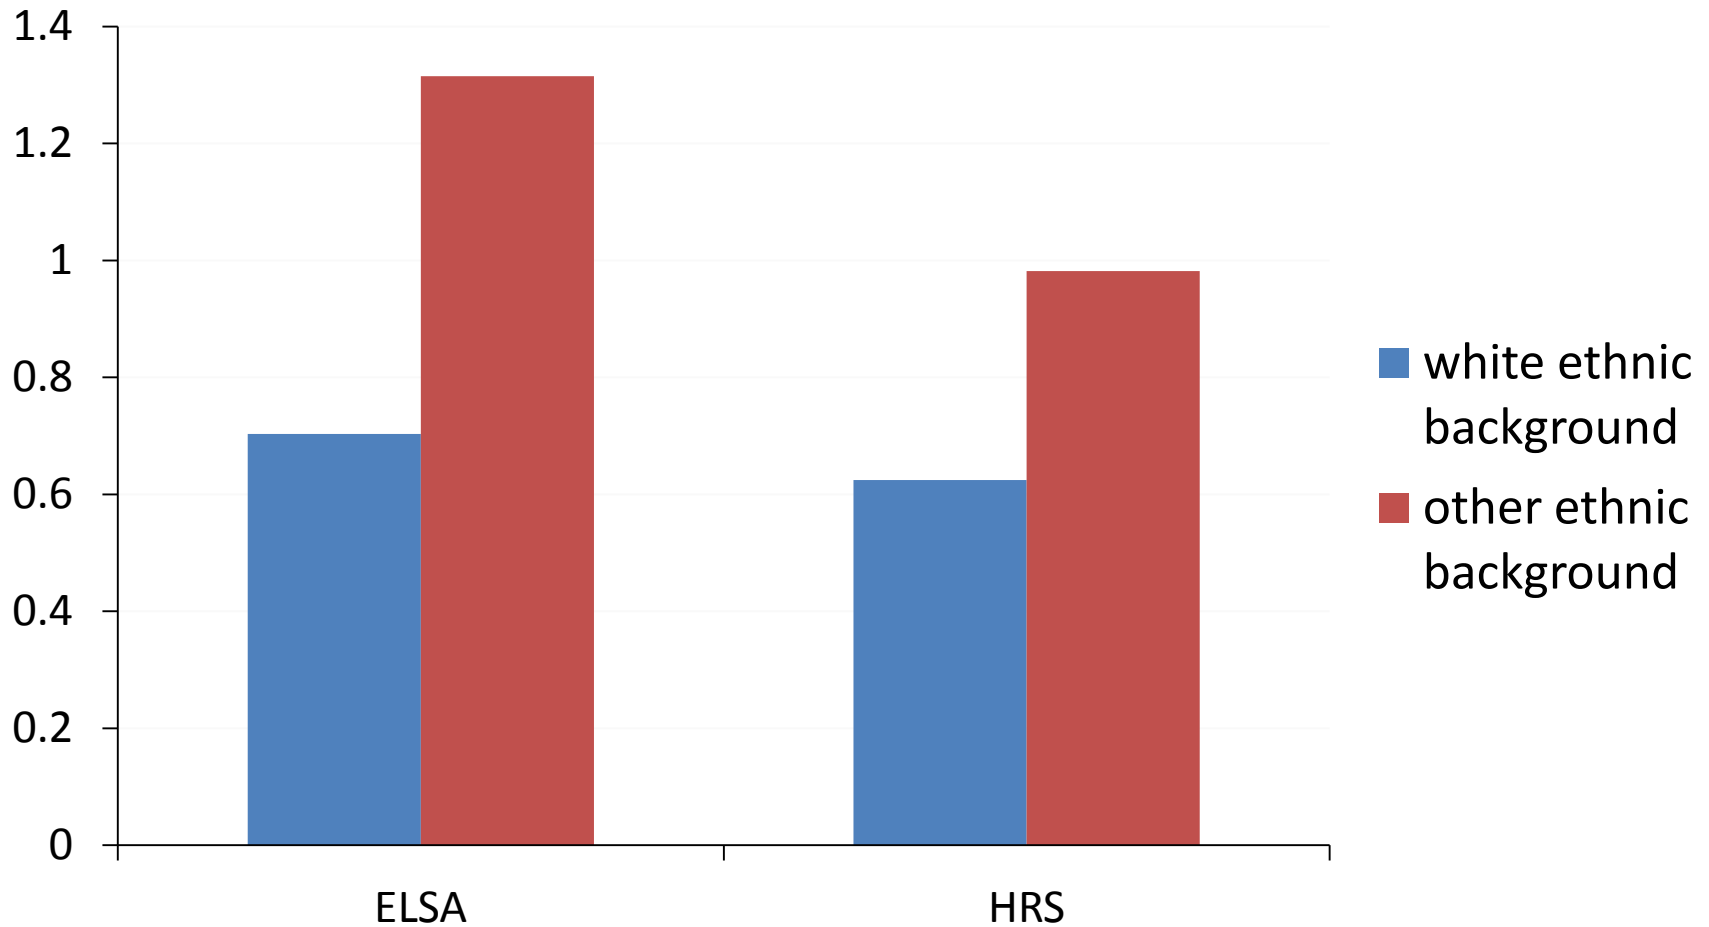

What's comparable?

- 'Ethnicity'
- *Employment status*
- *Marital status*
- Education
- *Wealth*
- *Limitations in activities of daily living*
 - > + interactions with gender/wave/country

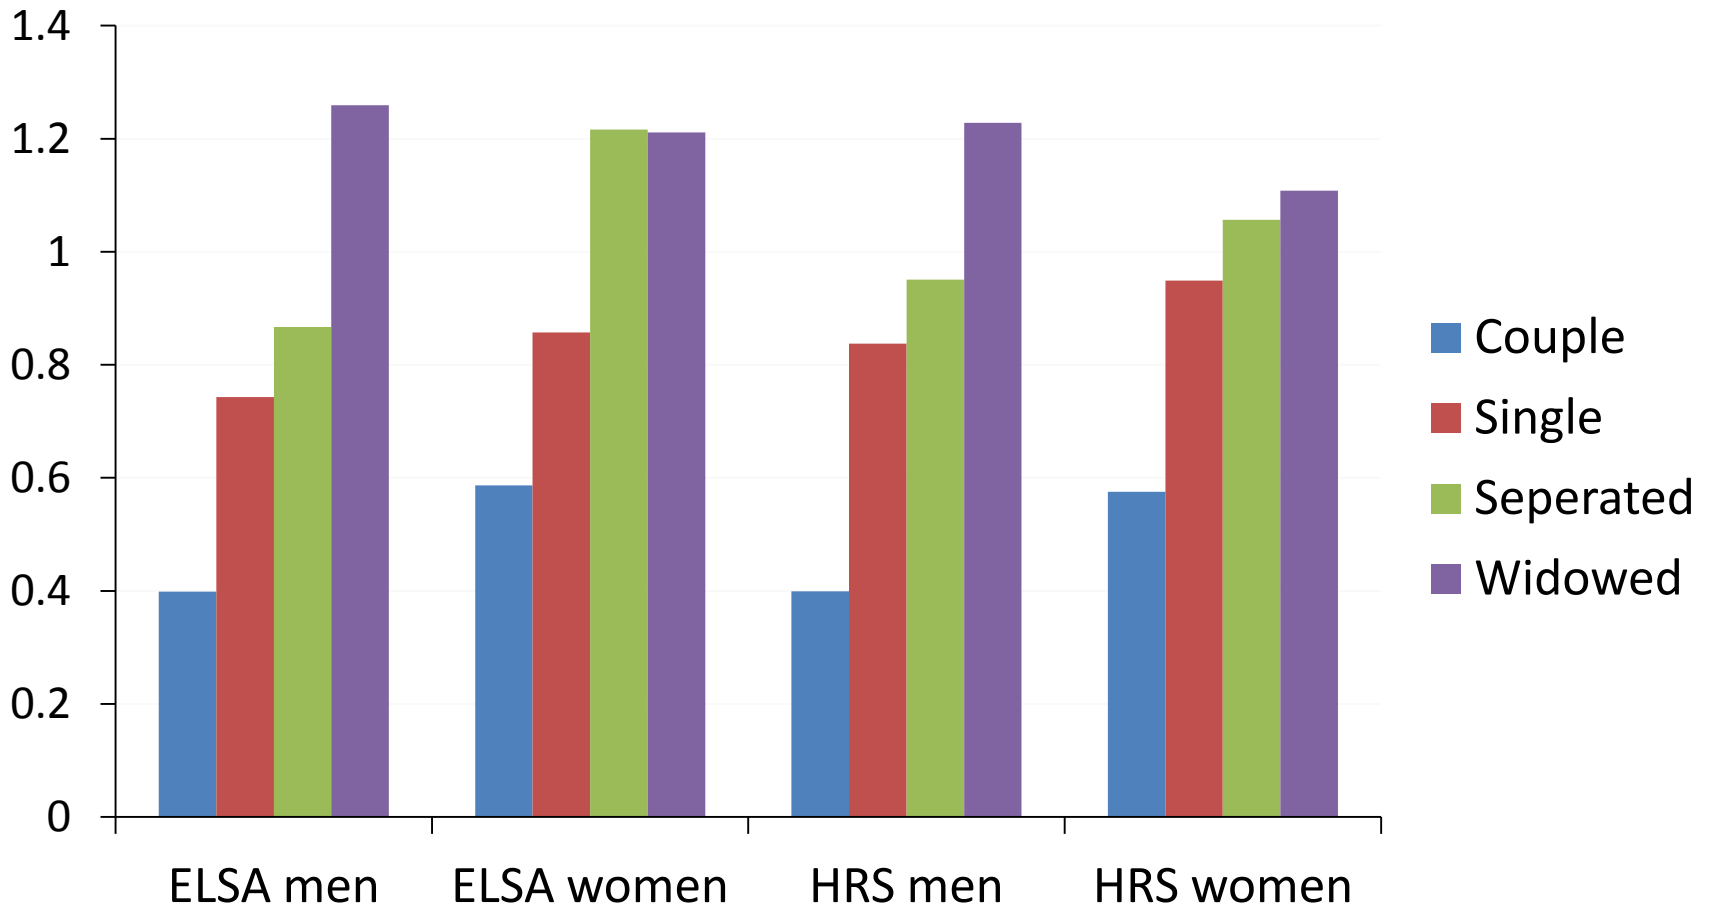

Gender, country and depressive symptoms

Ethnic differences in mood symptoms

Partner status and mood symptoms

Wealth gradient in mood

Educational differences in somatic symptoms

Somatic symptoms and adl

Conclusion: Measurement

- CESD has very good properties to be used for comparative studies
- In later life, it makes sense to distinguish mood symptoms from somatic symptoms
 - Mood more influenced by partnership status (especially for men)
 - Somatic symptoms more related to educational differences and limitations in ADL -> might not be clinical depression

Conclusion: Differential effects

- Being non-white or having a degree more associated with depressed mood in England compared to US
- Being single or having limitations in ADL gives higher chance for depressive symptoms in US

Conclusion: Background effects?

- The strongest sex: a construction of masculinity?
 - Suicide rates among men about 4 times higher
 - Coping works quite different between genders
- Psychotherapy culture in the USA:
 - Role of prior depression and treatment
